Synopsis A new polymorph of ferrocenecarboxylic anhydride was obtained, characterized and its structural features were compared to the other cyclopentadienyl carboxylic anhydrides.

Abstract A new polymorph of ferrocenecarboxylic anhydride which crystallise in the monoclinic crystalline system was obtained. Three molecules are present in the asymmetric unit, two of them nearly identical (RMSD 0.1726) with the iron atoms on the same side of the anhydride functional group. In the third molecule, the two iron atoms are located at opposite sides of the functional group (ferrocene/ferrocene torsion angle 146.2 °), a very unusual feature in metallocene anhydrides. An network of intermolecular weak hydrogen bonds was also disclosed.

Keywords: crystal structure; ferrocene; acid anhydride; hydrogen bonds; polymorph

1. Introduction

Anhydrides are a well-known class of acylation reagents widely used in organic synthesis. While they are usually prepared intentionally for synthetic use, serendipity sometimes joins the game and leads to unexpected new compounds, as it is the case for ferrocene carboxylic anhydride (**1**, Scheme 1). It was first reported in 1959 by Lau and Hart during studies to access ferrocene peroxide (Lau & Hart, 1959). By refluxing ferrocene carboxylic chloride (FcCOCl) with sodium peroxide, they isolated **1**, which was characterized by its melting point, IR spectrum and elemental analysis. The same year, Acton and Silverstein obtained **1** during the synthesis of ferrocene carboxamides from ferrocene carboxylic acid (FcCO₂H) in the presence of dicyclohexylcarbodiimide (Acton & Silverstein, 1959). Reference samples

were further prepared by the reaction of FcCOCl with water in the presence of pyridine. In 1966, Kupchik and Kiesel reported the unexpected formation of **1** during the reaction of FcCOCl with tri-butyl-tin hydride, supposed to deliver the corresponding ferrocenecarboxaldehyde or ester (Kupchik & Kiesel, 1966). A reference sample was also prepared, that time by reacting FcCOCl with FcCO_2Na . It is almost 40 years later that Runqiu and Qingmin reported the formation of **1** (up to 47%) during the synthesis of FcCOCl in the conditions described by Lau and Hart (Runqiu & Qingmin, 2001). In addition to the previously reported melting point, IR spectrum and elemental analysis, the ^1H NMR spectrum and mass analysis of ferrocene carboxylic anhydride were described. In 2004, Schetter and Speiser also reported the formation of **1** during the reaction of FcCO_2H with various carbodiimides (Schetter & Speiser, 2004). Finally, in 2016, McAdam and Simpson reported that **1** was isolated during the reaction of FcCO_2H with triphosgene as a by-product (McAdam & Simpson, 2016). In this case the crystals suitable for X-ray analysis were obtained and the solid-state structure has been determined.

Apart from these synthesis reports, **1** was sporadically used as a reagent. Wenzer was the first one to use it for the esterification of cholesterol in the presence of pyridine (Hoffmann *et al.*, 1980). In 1990, Eckert reported the amidation of H-Phe-O*t*Bu in the presence of trimethylamine and the reaction of **1** with bovine serum albumin in buffered solution (Eckert & Koller, 1990). In 2004, Kihara and Takata used **1** in the synthesis of a redox-active rotaxane (Kihara *et al.*, 2004). A ferrocene stopper was introduced by the esterification of an alcohol in the presence of catalytic amounts of $n\text{Bu}_3\text{P}$. The same year, Schetter and Speiser reported the amidation of 3-(triethoxysilyl)propylamine with **1** in the presence of a carbodiimide in 37% yield (Schetter & Speiser, 2004). Finally, in 2012, Burrows and Marken reported the post-functionalization of metal-organic frameworks with **1** to access new redox-active materials (Halls *et al.*, 2012). It is to note that, apart from the work of Kihara and Tanaka, the yields of ester and amide formations remain surprisingly low (20 to 47%). This lack of reactivity was also noticed by Runqiu and Qingmin who failed to react **1** with primary or secondary amines and with hydrazines (Runqiu & Qingmin, 2001).

It appears that **1** is usually obtained as a by-product in the synthesis of FcCOCl with various chlorinating reagents or during the formation of amides in the presence of carbodiimides. In the course of a program dedicated to the synthesis of new ferrocene carboxamides (Palabindela *et al.*, 2016), we reacted FcCO_2H with thionyl chloride to access FcCOCl . During the purification steps, column chromatography afforded an unknown product, and ^1H and ^{13}C NMR studies revealed the presence of a monosubstituted ferrocene with a carboxyl group, which was not an acid, an acyl chloride, nor an ester. While the possibility of a stable anhydride raised in our minds, slow crystallization of the pure product occurred, and the solid-state structure obtained by X-ray diffraction confirmed our hypothesis. However, instead of the known crystal structure already described by McAdam and Simpson (McAdam & Simpson, 2016), we managed to obtain a previously unknown polymorph of **1**. Its spectroscopic data and crystal structure will be described here and compared to other cyclopentadienyl (Cp) carboxylic anhydrides.

2. Experimental

2.1. Synthesis and crystallization

Dimethylformamide (0.1 ml) and SOCl_2 (6.4 ml, 88 mmol, 2.2 eq.) were added dropwise to a suspension of FcCO_2H (9.2 g, 40 mmol, 1.0 eq.) in dry dichloromethane (110 ml) at room temperature (Scheme 2). After 15 min, the reaction mixture was concentrated under vacuum and the residue was dissolved in dry dichloromethane (150 ml) before diisopropylamine (17 ml, 120 mmol, 3.0 eq.) was added dropwise. The reaction mixture was then stirred at room temperature until reaction completion. HCl (1M) was added until pH 1 and the reaction mixture was extracted with EtOAc . The combined organic layers were dried over MgSO_4 , filtrated and concentrated under vacuum to give the crude product. Purification by column chromatography, eluting with heptane/ EtOAc (80:20) afforded the desired FcCOCl as the main product and the new ferrocene carboxylic anhydride polymorph **1B** by crystallization upon standing (0.18 g, 2%). Mp 113–116 °C.

2.2. Spectroscopic analyses

IR spectra were taken on a Perkin-Elmer Spectrum 100 spectrometer. ^1H and ^{13}C Nuclear Magnetic Resonance (NMR) spectra were recorded on a Bruker Avance III at respectively 500 MHz and 125 MHz. ^1H chemical shifts (δ) are given in ppm relative to the solvent residual peak and ^{13}C chemical shifts are relative to the central peak of the solvent signal. Peak assignments were based on two-dimensional experiments. ν_{max} (film)/ cm^{-1} 2919, 1768 (C=O, *sym*), 1713 (C=O, *asym*), 1444, 1243, 1067, 1044, 1007. ^1H NMR (500.0 MHz, CDCl_3): δ (ppm) 4.88 (t, J = 1.9 Hz, 4H, 4 x Fc CH), 4.54 (t, J = 1.9 Hz, 4H, 4 x Fc CH), 4.35 (s, 10H, 10 x Fc CH). ^{13}C NMR (125.7 MHz, CDCl_3): δ (ppm) 167.9 (2 x C=O), 72.9 (4 x Fc CH), 71.0 (4 x Fc CH), 70.4 (10 x Fc CH), 69.6 (2 x Fc C).

2.3. Refinement

The crystal structure was solved in the non-centrosymmetric Cc space group by dual-space algorithm using the *SHELXT* program (Sheldrick, 2015), and then refined with full-matrix least-square methods based on F^2 (*SHELXL*) (Sheldrick, 2015). The use of combined TWIN and BASF instructions led to a Flack parameter value of 0.21(3), corresponding to a mixture of ~80% of a particular enantiomer and ~20% of the opposite one. All non-hydrogen atoms were refined with anisotropic atomic displacement parameters. H atoms were included in calculated positions. In the absence of restraints or constraints on ADP's of C51-C55 ring atoms, some B and C alerts appeared in the CHECKCIF procedure, due to large values of ADP max/min ratios, especially on C52 (ratio = 4.2) and C55 (ratio=3.5). Introduction of restraints by RIGU instructions applied on these C51-C55 atoms in SHELXL refinement led to decrease these ADP max/min ratios (4.0 and 3.2 respectively) and provided more realistic anisotropic atomic displacements on this Cp ring. No constraints were used to refine the other rings. CCDC 1553140.

3. Results and discussion

The molecular structures of previously described by Simpson orthorhombic polymorph (**1A**, Figure 1, top) obtained and the monoclinic polymorph (**1B**, Figure 1, bottom) feature various differences and the crystallographic data of both polymorphs are disclosed in Table 1. The crystal packing of **1B** is shown in Figure 2. Only one molecule is present in the asymmetric unit of **1A**, while three independent molecules crystallized in the unit of **1B**. It can be seen that the anhydride molecules comprising the Fe1/Fe2 and Fe5/Fe6 atoms appear nearly identical by a 180 ° rotation around the b axis. This is confirmed by their molecular overlay (Mercury automatic overlay module was used), with the metal atom (Fe1/Fe2 and Fe5/Fe6) located on the same side of the anhydride (Figure 3, bottom, RMSD of 0.1726). However, much larger difference can be seen with the remaining anhydride molecule in which the two metal atoms (namely Fe3 and Fe4) are at the opposite sides on the anhydride, as confirmed by the overlay of molecules containing Fe1-Fe2 and Fe3-Fe4 (Figure 4, top right, RMSD 2.0862) and molecules containing Fe3-Fe4 and Fe5-Fe6 (Figure 4, top left, RMSD 2.1374). A packing similarity search (Mercury Solid Form module used, 20% distance tolerance, 20 ° angle tolerance, H-position and bound type ignored, structure inversion allowed) revealed one hit between the known orthorhombic polymorph **1A** and the anhydride molecules containing the Fe1 and Fe2 atoms of the new monoclinic polymorph **1B**. Indeed, as shown in figure 4, a moderate overlap can be seen with a RMSD of 0.624.

Figure 4 clearly shows why an intramolecular hydrogen bond occurred on **1A** (C206-H206···O1) and not on **1B** (C2-H2···O15): both H···A distances (**1A**: 2.56 Å, **1B**: 3.34) and D-H···A angles (**1A**: 148.9°, **1B**: 140.9) are more favorable to develop these weak interactions in **1A**. In addition to this intramolecular hydrogen bond, three intermolecular (C205-H205···O2, C204-H204···O1, C207-H207···O2) contacts, supporting the zig-zag chains of molecules along the a axis, were observed by the authors in **1A**. In **1B**, although no traditional H-bond donors are present, each carbonyl group can act as a weak hydrogen bond acceptor (Steiner, 2002; Desiraju, 2011). Although no zig-zag chains as present in **1A** could be seen in **1B**, we here identified a set of weak hydrogen bonds (Table 2). Along the b and c axes, four hydrogen bonds structure the packing (C85-H85···O42, C49-H49···O72, C31-H31···O12, C5-H5···O45) whereas three other ones (C6-H6···O15, C39-H39···O45 and C69-H69···O75) link molecules along the a axis [symmetry codes: (i) $x-1/2, -y+1/2, z+1/2$; (ii) $x, -y+1, z-1/2$; (iii) $x-1, y, z$; (iv) $x+1, y, z$] (Figure 5).

It is difficult to assess if the large Fc-Fc torsion angle (146.2°), placing the two ferrocene moieties at opposite sides of the anhydride group in one of the molecules of **1B**, is it the result or the origin of the C31-H31···O12 hydrogen bond. Therefore, to get more information on this large angle, we also compared the new polymorph **1B** to the five other examples of Cp-based carboxylic anhydrides for which a solid-state structure was reported (Scheme 3): trovacencarboxylic anhydride (**2**, Elschenbroich *et al.*, 1997, NEWFIE, CCDC 1219005), 1,1'-(*tert*-butoxycarbonyl)amino)ferrocenecarboxylic

anhydride (**3**, Siebler *et al.*, 2010, KAJBUU, CCDC 769441), ruthenocenecarboxylic anhydride (**4**, Micallef *et al.*, 2011, IVOYOI, CCDC 794550) and the ferrocenecyclophane **5** (Liu *et al.*, 2015, HOVYEY, CCDC 1038498). Our goal was therefore to see if the structure of **1B** was closer to the free rotating anhydrides **2** and **4** or to geometrically restrained ones such as **3** (due to the presence of a hydrogen bond between the two *tert*-butoxycarbonyl groups) and **5** (cyclophane structure).

In **1B**, the torsion angles measured for the three anhydride molecules (O12-C11…C14-O15, O42-C41…C44-O45 and O72-C71…C74-O75) are lower than those observed for the free rotating anhydrides **1A**, **2** and **4** (Table 3). Furthermore, the torsion angles between the two ferrocenyl cores of each anhydride molecule of **1B** are outside the usual range of values. This suggests that the polymorph **1B** is closer to geometrically restrained metallocene anhydrides than to the polymorph **1A**.

Intramolecular dihedral angles between the Cp rings are in good agreement with those observed for the other derivatives. However, two Cp rings of one ferrocenyl core of **1B** are clearly eclipsed with a C40-Cg3b…Cg3a-C35 torsion angle of 17.1°. This results from the hydrogen bond C31-H31…O12, which mimics the interactions observed in the 1,1'-disubstituted ferrocene-based anhydride **3**. For all six ferrocenyl cores, the angles between Cp ring planes are within the expected range of values, indicating the almost coplanarity of the Cp rings.

The angles between each carbonyl group and their respective Cp ring were finally compared. A comparison of the torsion angles of **1A–5** clearly shows that, as the geometry is constrained (intramolecular hydrogen bond in **3**, cyclophane structure in **5**), high values are observed (**3**: 19.4°, **5**: 21.7°). Such a torsion might be viewed as another mechanism to relieve steric strain. The torsion angles measured on the three molecules that crystallize in **1B** are between the ones of the unconstrained anhydrides (**1A**, **2**, **4**) and those of the constrained **3** and **5**. Accordingly, this suggests that steric strain exists at a higher degree in the new monoclinic polymorph, when compared to the orthorhombic one. Therefore, this higher strain in **1B** might have an effect on the thermodynamic stability of the polymorph.

Indeed, the density rule, as introduced by Burger and Ramberger (Burger & Ramberger, 1979), states that, at absolute zero, the most stable polymorph will have the highest density. However, the density difference between **1A** and **1B** (1.661 and 1.667 g/cm³ for **1A** and **1B**, respectively) is too small to apply this rule. Therefore, it appears difficult to clearly state which polymorph is here the more stable, although the lower melting point of **1B** (113–116 °C), when compared to **1A** (140–141 °C), suggests a higher stability for the orthorhombic polymorph **1A**.

Supporting information

Ferrocenecarboxylic anhydride: identification of a new polymorph

Mehdi Tazi^a, Thierry Roisnel^b, Florence Mongin^a and William Erb^{a*}

Computing details

Data collection: Bruker *APEX2* (Bruker, 2014). Cell refinement: Bruker *APEX2* (Bruker, 2014). Data reduction: Bruker *APEX2* (Bruker, 2014). Program(s) used to solve structure: *SHELXT* (Sheldrick, 2015). Program(s) used to refine structure: *SHELXL2016/6* (Sheldrick, 2015). Molecular graphics: SXGRAPH (Farrugia, 1999), *Mercury* (CSD, 2016). Software used to prepare material for publication: CRYSCALC (T. Roisnel, local program, 2017).

Ferrocenecarboxylic anhydride, monoclinic polymorph (1B)

Crystal data

$C_{22}H_{18}Fe_2O_3$	$F(000) = 2712$
$M_r = 442.06$	$D_x = 1.661 \text{ Mg m}^{-3}$
Monoclinic, Cc	Mo $K\alpha$ radiation, $\lambda = 0.71073 \text{ \AA}$
$a = 5.9758 (5) \text{ \AA}$	Cell parameters from 9522 reflections
$b = 36.456 (3) \text{ \AA}$	$\theta = 2.2\text{--}27.5^\circ$
$c = 24.363 (2) \text{ \AA}$	$\mu = 1.66 \text{ mm}^{-1}$
$\beta = 91.997 (3)^\circ$	$T = 150 \text{ K}$
$V = 5304.4 (8) \text{ \AA}^3$	Prism, red
$Z = 12$	$0.56 \times 0.36 \times 0.30 \text{ mm}$

Data collection

APEXII, Bruker-AXS	10804 independent reflections
diffractometer	
Radiation source: fine-focus sealed tube	10350 reflections with $I > 2\sigma(I)$
Graphite monochromator	$R_{\text{int}} = 0.023$
CCD rotation images, thin slices scans	$\theta_{\max} = 27.5^\circ$, $\theta_{\min} = 3.4^\circ$
Absorption correction: multi-scan	$h = -6 \rightarrow 7$
[Sheldrick, G.M. (2014). SADABS Bruker AXS Inc., Madison, Wisconsin, USA]	
$T_{\min} = 0.486$, $T_{\max} = 0.608$	$k = -46 \rightarrow 41$
16323 measured reflections	$l = -31 \rightarrow 31$

Refinement

Refinement on F^2	Hydrogen site location: inferred from neighbouring sites
Least-squares matrix: full	H-atom parameters constrained
$R[F^2 > 2\sigma(F^2)] = 0.049$	$w = 1/[O^2(F_o^2) + (0.0346P)^2 + 44.5361P]$
$wR(F^2) = 0.120$	where $P = (F_o^2 + 2F_c^2)/3$
$S = 1.11$	$(\Delta/\sigma)_{\max} = 0.006$
10804 reflections	$\Delta\rho_{\max} = 0.96 \text{ e \AA}^{-3}$
730 parameters	$\Delta\rho_{\min} = -0.87 \text{ e \AA}^{-3}$
32 restraints	Absolute structure: Flack x determined using 4113 quotients $[(I+)-(I-)]/[(I+)+(I-)]$ (Parsons et al., 2013).
	Absolute structure parameter: 0.204 (11)

Special details

Geometry. All esds (except the esd in the dihedral angle between two l.s. planes) are estimated using the full covariance matrix. The cell esds are taken into account individually in the estimation of esds in distances, angles and torsion angles; correlations between esds in cell parameters are only used when they are defined by crystal symmetry. An approximate (isotropic) treatment of cell esds is used for estimating esds involving l.s. planes.

Refinement. Refinement of F^2 against ALL reflections. The weighted R-factor wR and goodness of fit S are based on F^2 , conventional R-factors R are based on F, with F set to zero for negative F^2 . The threshold expression of $F^2 > 2\sigma(F^2)$ is used only for calculating R-factors(gt) etc. and is not relevant to the choice of reflections for refinement. R-factors based on F^2 are statistically about twice as large as those based on F, and R-factors based on ALL data will be even larger. Crystal structure was solved in the non-centrosymmetric Cc space group by dual-space algorithm using the *SHELXT* program (Sheldrick, 2015), and then refined with full-

matrix least-square methods based on F^2 (*SHELXL*) (Sheldrick, 2015). The use of combined TWIN and BASF instructions led to a Flack parameter value of 0.21(3), corresponding to a mixture of ~80% of a particular enantiomer and ~20% of the opposite one. All non-hydrogen atoms were refined with anisotropic atomic displacement parameters. H atoms were finally included in their calculated positions. A final refinement on F^2 with 10804 unique intensities and 683 parameters converged at $\omega R(F^2) = 0.1201$ ($R(F) = 0.0500$) for 10350 observed reflections with $I > 2\sigma(I)$. In the absence of restraints or constraints on ADP's of C51-C55 ring atoms, some B and C alerts appeared in the CHECKCIF procedure, due to large values of ADP max/min ratios, especially on C52 (ratio = 4.2) and C55 (ratio=3.5). Introduction of restraints with the help of RIGU instructions applied on these C51-C55 atoms in SHELXL refinement lead to decrease these ADP max/min ratios (4.0 and 3.2 respectively) and provided more realistic anisotropic atomic displacements on this CP ring. No constraints were used to refine the other cycles. CCDC 1553140.
