Synopsis TOC

Abstract

1
2
3 The synthesis of a series of twenty new 2,4,6-tristyrylpyrimidines and three new 2,4-
4 distyrylpyrimidines by means of combination of Knoevenagel condensation and Suzuki-
5 Miyaura cross coupling reaction is reported. This methodology enables to obtain
6 chromophores with identical or different substituent on each arm. The photophysical
7 properties of the compounds are described. Optical properties and TD-DFT calculations
8 indicate that photophysical properties of target compounds are mainly affected by the nature
9 of the electron-donating group in C4/C6 positions, except when the C2 substituent is a
10 significantly stronger electron-donating group. However, the C2 substituent has a strong
11 influence on emission quantum yield: addition of a strong electron-donating group tends to
12 decrease the fluorescence quantum yield whereas a moderate electron-withdrawing group
13 results in a significant increase of fluorescence quantum yield.

28 **Introduction**

29
30
31 During the past two decades, there has been a great interest in the synthesis of
32 pyrimidine fluorophores.¹ The pyrimidine is a six-membered heterocycle with two nitrogen
33 atoms (1,3-diazine) that exhibits a strong electron-withdrawing character. When the
34 pyrimidine ring is combined with electron-donating fragments via π -conjugated linkers,
35 intramolecular charge transfer (ICT) occurs leading, generally, to a strong emission.¹
36
37 Recently, pyrimidine-based thermally activated fluorescent emitters (TADF) have been
38 developed and have been used for high external quantum efficiency organic light-emitting
39 diodes (OLEDs).² 4,6-Distyrylpyrimidines have also been developed as two-photon excitation
40 emitters for biological microscopy³ and photoinitiator for multiphoton lithography.⁴
41
42 Due to the electron lone pair of its two nitrogen atoms, the pyrimidine ring can catch protons,
43 coordinate metal cations, and link to various (bio)organic molecules leading to modification
44 of its emission properties. Various pyrimidine chromophores have been used as pH,⁵ metal

cations,⁶ nitroaromatic⁷, and protein⁸ fluorescent sensors. Mixtures of neutral and protonated forms of pyrimidine fluorophores have also been used as white light emitters.⁹ Recently, Kato and coworkers have highlighted the influence of substituent in C2 position on the emission properties of pyrimidine derivatives.¹⁰

Y-shaped centripetal molecules have been subject to intensive research.¹¹ In this context, the triazine core has been extensively used.¹² In these structures, periphery-to-core multidimensional charge transfer lead to large second-order optical response¹³ and large two photon absorption cross section.¹⁴ Numerous 2,4,6-triaryl- and 2,4,6-triarylethynylpyrimidine chromophores have been designed for their luminescence properties.^{15,16}

Styrylpyrimidines are generally obtained by Knoevenagel condensation of an aldehyde with methylpyrimidine under basic or acidic conditions.^{4,5,8,9a,10,17} This reaction can be easily carried out on the methyl group in positions C2, C4 and/or C6. Using this strategy, 2-styryl,¹⁸ 4-styryl^{3c,9a,17} and 4,6-distyrylpyrimidine^{3,4,5a,8,10,17} as well as 4,4',6,6'-tetrastyrylpyrimidine¹⁹ chromophores have been prepared so far; selected known 4,6-distyrylpyrimidines are presented in Chart 1. To the best of our knowledge, only the unsubstituted 2,4,6-tristyrylpyrimidine has been described to date.²⁰

Chart 1. Structures of selected known chromophores 4,6-distyrylpyrimidines.^{5a,17a}

In this contribution, we describe the design and synthesis of 2,4,6-tristyrylpyrimidines and 2,4-distyrylpyrimidines by combining Suzuki-Miyaura cross coupling reaction and Knoevenagel condensation. This strategy enables the synthesis of compounds with different substituents on each arm and, thus, allows modification of their electron donating or withdrawing abilities. The molecular structure obtained by X-ray analysis of a selected

1
2
3 chromophore is also described. The photophysical properties of target chromophores were
4
5 studied and thoroughly compared with the corresponding 4,6-distyrylpyrimidines. The DFT
6
7 and TD-DFT calculations were also performed on selected chromophores to rationalize their
8
9 photophysical properties.
10

11 12 13 **Results and discussion**

14 15 **Synthesis**

16
17 Various strategies have been considered for the synthesis of 2,4,6-tristyrylpyrimidines.
18
19 Threefold Knoevenagel condensation from 2,4,6-trimethylpyrimidine has been envisioned.
20
21 However, the pyrimidine starting material cannot be isolated easily in a good yield.²¹ The
22
23 synthesis of 2-methyl-4,6-distyrylpyrimidine was also considered by treating 4,6-
24
25 distyrylpyrimidine with methyllithium followed by *in-situ* rearomatization with DDQ
26
27 according to known procedure²² but we failed in obtaining the desired product. We therefore
28
29 proposed a third strategy, starting from commercially available 2-chloro-4,6-
30
31 dimethylpyrimidine and 2,4-dichloro-6-methylpyrimidine. A combination of Suzuki cross-
32
33 coupling and Knoevenagel condensation has been developed leading to twenty-one
34
35 tristyrylpyrimidine chromophores (Schemes 1–2).
36
37

38
39 Chromophores **2** with identical substituents in C4 and C6 positions were obtained in two steps
40
41 from 2-chloro-4,6-dimethylpyrimidine. The first step consists of the *in-situ* conversion of
42
43 arylalkynes into styrylboronic acid by action of catecholborane followed by palladium-
44
45 catalyzed Suzuki-Miyaura cross coupling reaction.²³ 2-Styrylpyrimidine intermediates **1** were
46
47 obtained in moderate to good yields. 2,4,6-Tristyrylpyrimidines **2** were obtained by
48
49 condensation between the C4 and C6 methyl group and the corresponding aromatic aldehyde
50
51 in boiling aqueous 5 M NaOH using Aliquat 336 as catalyst.^{5a,17a} Moderate to good yields
52
53
54
55
56
57
58
59
60

were generally observed. The lower yields, observed in particular for unsubstituted styryl derivatives, were due to more complicated purification process.

Scheme 1: Synthesis of compounds **2**.

To obtain 2,4,6-tristyrylpyrimidines **5** with three different arms, a three-step synthetic route employed 2,4-dichloro-6-methylpyrimidine as a starting material (Scheme 2). The first step consisted in a C4 regioselective Suzuki-Miyaura cross coupling reaction with *in situ* formed styrylboronic acid leading to intermediates **3**. The observed regioselectivity of cross coupling reaction in C4 over C2 position of the pyrimidine ring is in accordance with the literature.^{15b,16a,24} The second step consisted in a second Suzuki-Miyaura cross coupling reaction in C2 position leading to 2,4-distyrylpyrimidines intermediates **4** and finally a Knoevenagel condensation of 4-(*N,N*-diphenylamino)benzaldehyde on the methyl group in C6 position lead to chromophores **5**.

- (i): catecholborane, THF, reflux, 3.5h
 (ii): 2,4-dichloro-6-methylpyrimidine, Pd(PPh₃)₄, Na₂CO₃, reflux, 15h
 (iii): **3a** or **3b**, Pd(PPh₃)₄, Na₂CO₃, reflux, 15h
 (iv): 4-R³-C₆H₄-CHO, aliquat 336, NaOH aq 5M, reflux, 3h

Scheme 2: Synthesis of compounds 5.

Starting from 2-chloro-4-methylpyrimidine, 2,4-distyrylpyrimidines were obtained in a similar two-step synthetic pathway (Scheme 3).

(i): catecholborane, THF, reflux, 3.5h
 (ii): 2-chloro-4-methylpyrimidine, Pd(PPh₃)₄, Na₂CO₃, reflux, 15h
 (iii): 4-R-C₆H₄-CHO, aliquat 336, NaOH aq 5M, reflux, 3h

Scheme 3: Synthesis of compounds 7.

All new compounds are well soluble especially in chlorinated solvents (DCM, CHCl₃) and were characterized by ¹H, ¹³C NMR and HRMS spectroscopic techniques. The selectivity of the Suzuki-Miyaura cross coupling as well as condensation reactions was sufficiently high to generate all *trans*-isomer within the limits of NMR detection as observed previously.^{5a} The stereochemistry of the double bonds was unequivocally established on the basis of coupling constant for the vinylic proton in the ¹H NMR ($J \approx 16$ Hz). No *trans/cis* isomerisation were observed during photophysical experiments.

X-ray Analysis

Chromophore **2h** provided crystals for X-ray analysis by slow evaporation of its dichloromethane/ethyl acetate (1/1, v/v) solution. The measured crystal, a large fragment of a large yellow and transparent prism, confirms the proposed molecular structure; in particular the *E* configuration of the three vinylic linkers is confirmed (Figure 1). An orthorhombic crystal system is observed with a Pna2₁ space group. The presence of a (modelled) disorder

1
2
3 on one of the two C4/C6 arm, already observed for similar structures,^{19b} can be shown. Solid
4
5 state supramolecular assembly of the chromophore revealed an orthorhombic crystal system
6
7 with a Pna2₁ space group. The crystal structure shows that the angles between the planes of
8
9 three benzene rings and the pyrimidine central core lower than 20°, indicating that they are
10
11 not completely planar, in accordance with other 4-styryl- and 4,6-distyrylpyrimidines.^{9a,25} It
12
13 should be noted that the dihedral angle between the phenyl ring in C2 position and the
14
15 pyrimidine core is the lowest (~7°). Bond length alternation (BLA) were calculated for the
16
17 vinylic linker on each arm and were revealed to be slightly lower for the C2 arm (0.1185 Å),
18
19 than for C4/C6 arms (0.1205, 0.1600 and 0.1775 Å) indicating that the C2 arm imparts
20
21 stronger ICT.

Thermal properties

Thermal behaviour of the final compounds **2**, **5** and **7** as well as compounds **A₂** and **A₃** was studied by differential scanning calorimetry (DSC). Figure 2 shows thermograms of representative compounds **2i**, **2m**, **A₂** and **A₃** while Table 1 lists all measured melting points (T_m) and temperatures of thermal decompositions (T_d). All DCS curves are given in the SI. The measured melting points range from 128 to 243 °C. The temperature of decomposition was estimated within the range of 195-320 °C. Further discussion on the thermal properties is provided in the SI.

Figure 2: Representative DSC thermographs of compounds **2i**, **2m**, **A₂** and **A₃** obtained with a scanning rate of 3°C/min in the range 50-400°C

Table 1: DSC results for chromophores **2**, **5**, **7**, **A₂** and **A₃**.

Comp.	T_m (°C)	T_d (°C)	Comp.	T_m (°C)	T_d (°C)	Comp.	T_m (°C)	T_d (°C)	Comp.	T_m (°C)	T_d (°C)
2a	193	300	2h	200	295	2o	/	250	7a	137	290
2b	128	290	2i	/	250	2p	/	220	7b	185	305
2c	/	245	2j	/	240	2q	/	280	7c	243	265
2d	/	305	2k	/	310	2r	210	265	7d	/	250

2f	/	250	2m	/	310	5a	/	240	A₃	205	320
2g	/	270	2n	/	290	5b	/	210			

T_m = melting point (the point of intersection of a baseline and a tangent of thermal effect = onset). T_d = thermal decomposition (pyrolysis in N₂ atmosphere).

Common feature of tripodal (D- π)₃-A or (D- π)₂-A-(π -A) chromophores **2a-s** and **5a-b** is their resistance to crystallize and they often occur as solid glasses and amorphous solid. This suggests a more sophisticated thermal behaviour of centripetal star-shaped systems. Hence, their DSC curves are frequently similar and decorated by solid-solid or glass transitions. Based on the DSC analysis there are no evident general trends between type or position of particular donor used and thermal behavior of tripodal chromophores. Structural

1
2
3 modifications (donor variation) often influences the thermal properties of tripodal
4 chromophores only negligibly because the intrinsic nature of these molecules remains the
5 same.
6
7

8
9 In general, 2,4- and 4,6-disubstituted pyrimidines (**7a–d**, **A₂** and **A₃**) have
10 demonstrated a similar thermal behaviour. A presence of donor groups (NMe₂, OMe) in
11 quadrupolar molecules **7b** and **7c** increases the melting point up to 100 °C compared to
12 “donor free” analogue **7a**.
13
14
15

16
17 The *T_d* of tripodal molecules **2i/2m** and their quadrupolar analogous **A₂/A₃** are
18 comparable (Figure 2) and dictated by the type of attached donors on the periphery.
19 Therefore, DMA **2i/A₂** and TPA analogous **2m/A₃** have demonstrated almost identical *T_d*
20 values (250/260 and 310/320 °C, see Table 1).

28 **Photophysical properties**

29
30 The UV/Vis and photoluminescence (PL) spectroscopic data of compounds **2**, **5** and **7**
31 measured in CH₂Cl₂ at room temperature are presented in Table 2. The analyses were carried
32 out by using low concentrations of chromophores (0.5–1.5 × 10⁻⁵ M). To facilitate comparison
33 of photophysical properties, 4,6-distyrylpyrimidines **A^{5a}** were also included in Table 1. As an
34 example, the spectra of compounds **2b**, **2c** and **2d** are provided in Figure 3.

Figure 3: Normalized absorption (solid lines) and emission spectra (dashed lines) of compounds **2b** (black), **2c** (green) and **2d** (green) in CH_2Cl_2 solution.

For all the compounds, the less energetic absorption band ($\lambda_{\text{max}} = 312\text{-}429$ nm) is attributed to charge transfer. Except compounds **2a**, **2h**, **7a** and **7b**, that are however slightly emissive in non polar heptane, all the compounds exhibit significant emission. In case of **2h**, the absence of emission is attributed to twisted intramolecular charge transfer excited state. For these compounds, as generally observed for pyrimidine push-pull chromophores,¹ large Stokes shifts were obtained, indicating large difference (vibrational, electronic, geometric) between the Franck-Condon state and the excited state. For tristyrylpyrimidines **2** and **5**, the position of absorption and emission wavelength maxima depends mainly on C4/C6 substituents. However, it should be noted that a significant red-shift in emission is observed when the C2

substituent is a significantly stronger electron-donating groups than C4/C6 substituents (**2j** and **2k**). Whereas the ICT generally occurs over the C4/C6 arm, in this case, the ICT is probably prevailing on the C2 arm. The fluorescence quantum yield varies significantly when the C2 substituent is modified. When tristyrylpyrimidines **2b-2d** with unsubstituted styryl group in C2 position are compared with 2,6-distyrylpyrimidines **A1-A3**, it appears that the addition of the styryl group in C2 position leads to a slight red shift of the emission maxima and a significant increase of the fluorescence quantum yield. The presence of an electron-donating group (methoxy, dimethylamino or diphenylamino) on the C2 arm (compounds **2e-2g**, **2i**, **2l**, **2m**) results in a slight blue shift of emission regarding the corresponding unsubstituted styryl derivatives **2b-2d**. The opposite trend is observed for **2j** and **2k** probably due to change in the ICT direction over the C2 arm. Whereas chromophores with dimethylamino group on C4/C6 arms (compounds **A2**, **2c**, **2f**, **2l**, **2o**, **2r** and **5a**) are generally highly luminescent, the incorporation of this fragment on C2 (chromophores **2h-2j**, **5b** and **7c**) leads to a dramatic decrease of fluorescence quantum yield. On the other hand, the addition of a trifluoromethyl fragment, a moderately electron-withdrawing group, on C2 arm (chromophores **2q-2s**) results in a significant increase of the fluorescence quantum yield up to 1.00 for **2s**. 2,4-Distyrylpyrimidines **7** exhibits significantly blue shifted absorption and emission with regards to their 4,6-distyryl and 2,4,6-tristyrylpyrimidines analogues. All these trends are in accordance with the observation made on arylpyrimidine series.^{1a,15a-b}

^a All spectra were recorded at room temperature at $c = 0.5 \times 10^{-5}$ M to 1.5×10^{-5} . ^b Fluorescence quantum yield ($\pm 10\%$) determined relative to 9,10-bisphenylethynylanthracene in cyclohexane ($\Phi_F = 1.00$).²⁶

In order to gain further insights into the photophysical properties of these compounds, their absorption and emission behavior was studied in a variety of aprotic solvents. While the absorption maxima were not significantly shifted, an increase in solvent polarity, estimated by Dimroth-Reichardt polarity parameter,²⁷ led to bathochromic shifts of the emission maxima. The results of emission solvatochromism are summarized in Table 3. As an example, the spectra registered for compound **2g** are shown in Figure 4 and the change in emission color under UV irradiation for compound **2k**, easily seen by the naked eye, can be seen in Figure 5. This solvatochromic behavior, characteristic for fluorophore featuring intramolecular charge transfer, can be explained by the stabilization of the highly polar emitting state by polar solvents.²⁸ For all the compounds, the emission maxima were plotted *versus* Dimroth-Reichardt polarity parameter (see Figures S106-S112) and, in all cases, a good linearity was observed. The emission solvatochromic behavior can be quantified by the slope of the corresponding regression line. Once again, with the exception of compound **2k**, the substituents in C4/C6 arm are the most affected by the emission solvatochromism with decreasing order: $\text{NMe}_2 > \text{NPh}_2 > \text{OMe}$. This is in accordance to the electron-donating strength of the substituents. The slopes for 2,4-distyrylpyrimidines **7c** and **7d** are significantly lower than that of their 2,4,6-tristyrylpyrimidine analogues **2i** and **2m**, indicating that both arms in C4 and C6 position play a role on the emission solvatochromism and, therefore on ICT into the chromophores.

Table 3: Emission solvatochromism of pyrimidine derivatives in various aprotic solvents.

^a Dimroth–Reichardt polarity parameter, kcal·mol⁻¹

Figure 4: Normalized emission spectra of **2g** in different aprotic solvents.

Figure 5: Fluorescence color changes experienced by **2k** in various solvents. Picture was taken in the dark upon irradiation with a hand-held UV lamp ($\lambda_{em} = 366$ nm).

The ability of protonation of pyrimidine chromophores has been already demonstrated.^{5,9} Generally, the protonation of amino-substituted stryrylpyrimidines results in quenching of emission; however, in the case of less electron-donating substituents, such as methoxy groups,

1
2
3 the protonation lead to a red-shifted emission.^{5a,9a} The changes in the emission spectra of **2q**
4 upon addition of (1*S*)-(+)-10-camphorsulfonic acid are illustrated in Figure 6. The progressive
5 disappearance of the emission band of the neutral form at 441 nm is observed, whereas a new
6 red-shifted absorption band at 540 nm progressively appear corresponding to the
7 monoprotinated species.^{9a} As shown on Figure 7, the neutral form of **2q** emits dark blue light
8 under UV-irradiation whereas the protonated form emits green light. A mixture of the two
9 forms enables to obtain cyan light.

Figure 7 Change in the color of a CH_2Cl_2 solution of **2q** ($c = 0.9642 \times 10^{-5}$ M) after the addition of 0.8 equiv (middle) and 50 equiv of (1*S*)-(+)-10-camphorsulfonic acid (right). Picture was taken in the dark upon irradiation with a hand-held UV lamp ($\lambda_{\text{em}} = 366$ nm).

DFT calculations

DFT calculations implemented in Gaussian 16 software package²⁹ were employed to investigate the fundamental properties of representative pyrimidines **A3**, **2g**, **2j**, **2k**, and **2m** with a systematically varied structural arrangement. Their optimized geometries, the HOMO/LUMO energies, and ground state dipole moments μ (Table 4) were obtained by DFT B3LYP/6-311+g(2d,p) method. The calculated HOMO/LUMO levels were further visualized in the energy level diagram as shown in Figure 8. Whereas the HOMO-LUMO gaps of all molecules are almost identical (2.97-3.02 eV), the principal variations are seen at both HOMO/LUMO levels. Hence, decoration of the central pyrimidine acceptor with two or three donor arms affects the position of the HOMO and LUMO rather than the HOMO-LUMO difference. This is in accordance to our latest observation and generalization on multipodal chromophores.³⁰ The frontier molecular orbitals are further visualized in Figure 9. In the parent molecule **A3**, the HOMO is localized on both *N,N*-diphenylamino donors but is also

1
2
3 mixed with the LUMO spread over the central pyrimidine and adjacent π -linkers. This implies
4
5 lower charge separation. The situation is similar in **2g** bearing weak additional
6
7 4-methoxystyryl donor appended at C2 (the second *N,N*-diphenylamino donor is occupied by
8
9 the HOMO-1). However, by attaching strong electron releasing moieties, such as *N,N*-
10
11 dimethylamino or *N,N*-diphenylamino groups, the HOMO has completely moved on the arms
12
13 appended at C2 regardless what type of donors are connected at C4/C6. Hence, for **2j**, **2k**, and
14
15 **2m**, the ICT dominates from the arm connected at pyrimidine C2.

16
17
18 **Table 4:** DFT calculated data of representative chromophores.

Compd ^a	E_{HOMO} eV	E_{LUMO} eV	ΔE eV	μ D	λ_{max} nm/eV
A3	-5.26	-2.27	2.99	3.39	475/2.61
2g	-5.21	-2.19	3.02	2.00	468/2.65
2j	-5.09	-2.12	2.97	1.41	458/2.71
2k	-5.14	-2.13	3.01	3.89	403/3.08
2m	-5.14	-2.21	2.94	1.60	464/2.67

Figure 8 Energy level diagram of the DFT-derived HOMO/LUMO energies.

Figure 9 Optimized geometries and HOMO (red) and LUMO (blue) localizations in representative chromophores.

The electronic absorption spectra of representative chromophores were further calculated using TD-SCF (nstates = 10) B3LYP/6-311+g(2d,p) method. The spectra are listed in Figure S113 jointly with the experimental data; the calculated longest-wavelength absorption maxima are given in Table 3. Their correlation with the experimental λ_{max} values is very tight

1
2
3 as shown in Figure S114. This implies that, despite the calculated values are generally red-
4 shifted, the employed method is capable to described trends within the given series of
5 molecules. The spectra of representative chromophores feature a low energy lying CT-band
6 with the λ_{max} appearing between 403-475 nm (376-428 nm experimentally). Compared to
7 tripodal molecules **2**, the quadrupolar chromophore **A3** showed the most bathochromically
8 shifted CT-band ($\lambda_{\text{max}} = 428$ nm). This may be explained by the Frenkel exciton model, which
9 predicts splitting of the singlet excited state into two and three bands for quadrupolar and
10 tripodal molecules, as compared to their linear analogue. Whereas for quadrupolar molecules
11 is the low energy band dominant, the low energy lying two states of a tripodal molecule are
12 degenerate while the third high energy state has zero oscillator strength. Hence, the absorption
13 spectra of both types of molecules are characterized by a single CT-band, eventually
14 accompanied by a shoulder for quadrupolar molecules and a blue-shift for tripodal ones.
15 According to the performed calculations, the CT-bands of quadrupolar **A3** and tripodal **2g**,
16 bearing weak methoxy electron donor, are almost exclusively generated by the
17 HOMO→LUMO transition. On the other hand, the CT bands of **2j** and **2m**, bearing all amino
18 donors, are dominated by the HOMO→LUMO, HOMO-1→LUMO, and HOMO→LUMO+1
19 transitions. Replacement of two amino donors at C4/C6 as in **2k** led to a significantly red-
20 shifted HOMO→LUMO transition (~468 nm, see Figure S113) but with diminished oscillator
21 strength. Hence, the observed CT-band is generated by the HOMO→LUMO+1 and HOMO-
22 1→LUMO transitions.

23 24 25 26 27 28 29 30 31 32 33 34 35 36 37 38 39 40 41 42 43 44 45 46 47 **Conclusions**

48
49 In conclusion, we have successfully synthesized 2,4,6-tristyrylpyrimidine and 2,4-
50 distyrylpyrimidine chromophores with identical or different substituent on each arm. In terms
51 of absorption and emission maxima, and calculated HOMO-LUMO gaps, 2,4,6-
52 tristyrylpyrimidines exhibits generally the similar properties as the corresponding 4,6-
53
54
55
56
57

1
2
3 distyrylpyrimidines. Nevertheless, when the C2 substituent is a significantly stronger
4 electron-donating substituents than C4/C6 ones, the ICT occurs mainly on this branch and
5 dictates the photophysical properties. In all cases, the C2 substituent play a key role on the
6 emission quantum yield. As one would expected, all these materials exhibit strong emission
7 solvatochromism and pH sensibility. Comparison of the two-photon absorption properties of
8 2,4,6-tristyrylpyrimidine with the corresponding 4,6-distyrylpyrimidines are currently under
9 investigation.

18 **Experimental Section**

20 **General Conditions.** In air- and moisture-sensitive reactions, all glassware was flame-dried and
21 cooled under nitrogen. Thermal behavior of the target compounds was measured in open aluminous
22 crucibles under N₂ inert atmosphere. DSC curves were determined with a scanning rate of 3 °C/min
23 within the range 25–400 °C. NMR spectra were acquired at room temperature. Chemical shifts are
24 given in parts per million relative to TMS (¹H, 0.0 ppm) and CDCl₃ (¹³C, 77.0 ppm). Acidic impurities
25 in CDCl₃ were removed by treatment with anhydrous K₂CO₃. High resolution MALDI MS spectra
26 were measured on a MALDI mass spectrometer equipped with nitrogen UV laser (337 nm, 60 Hz) and
27 quadrupole analyser (positive-ion mode over a normal mass range (*m/z* 50-2000) with resolution
28 100 000 at *m/z* = 400). *Trans*-2-[3-(4-*tert*-butylphenyl)-2-methyl-2-propenylidene]malononitrile
29 (DCTB) was used as a matrix. Mass spectra were averaged over the whole MS record for all measured
30 samples. UV-vis and fluorescence spectra were recorded using standard 1 cm quartz cells. Compounds
31 were excited at their absorption maxima (band of lowest energy) to record the emission spectra. The
32 Φ_F values were calculated using a well-known procedure with 9,10-diphenylethynylanthracene in
33 cyclohexane as standard.²⁶ Stokes shifts were calculated by considering the lowest energetic
34 absorption band. All calculations were carried out in Gaussian 09W package at the DFT level of
35 theory. The initial geometry optimizations were carried out by the PM3 method implemented in
36 program ArgusLab and subsequently by the DFT B3LYP method using the 6-311G++(2d,f,p) basic

1
2
3 set. The energies of the HOMO and LUMO (E_{HOMO} and E_{LUMO}), their differences (ΔE) and ground
4
5 state dipole moments (μ) were calculated by the DFT B3LYP/6-311++G(2d,f,p) method.

6
7 **General procedure for Suzuki-Miyaura cross-coupling reaction.** The corresponding
8
9 acetylene (1.57 equiv) was dissolved in THF (20 mL) and nitrogen was bubbled through the
10
11 solution for 10 min. Catecholborane (1.9 equiv of 1 M solution in THF) was added and the
12
13 reaction mixture was heated to reflux for 1.5 h. The second portion of catecholborane (0.7
14
15 equiv) was added and heating was continued for 2 h. The reaction mixture was cooled to room
16
17 temperature and Pd(PPh₃)₄ (0.025 equiv) and corresponding pyrimidine (1 equiv) were added.
18
19 Solution was stirred for 20 min before 20% aqueous Na₂CO₃ (5 mL) was added and the
20
21 mixture was stirred under nitrogen at reflux for 15 h. The reaction mixture was cooled and
22
23 then diluted with CH₂Cl₂ (20 mL). The organic layer was washed with water (3x20 mL), then
24
25 with brine (20 mL), separated, dried over MgSO₄ and the solvents were evaporated under
26
27 reduced pressure. The crude product was purified by column chromatography (SiO₂, indicated
28
29 solvents).

30
31
32 **General procedure for Knoevenagel condensation.** Aldehyde (1 equiv) and corresponding
33
34 4-methylpyrimidine (1 equiv) or 4,6-dimethylpyrimidine (0.5 equiv) were added in 5 M
35
36 aqueous NaOH (15 mL) containing Aliquat 336 (0.1 equiv). Solution was heated to reflux for
37
38 3 h and then cooled to room temperature. The precipitate was filtered off, washed with water,
39
40 and purified by recrystallization from CH₂Cl₂/*n*-heptane and/or by column chromatography
41
42 (SiO₂, indicated solvents).

(SiO₂, petroleum ether:EtOAc, 8:2). Yield: 46 mg (61 %); orange solid. *R*_f: 0.5 (SiO₂; petroleum ether:EtOAc, 8:2). *T*_d: 240 °C. ¹H NMR (300 MHz, CDCl₃): δ = 3.03 (s, 6H), 3.85 (s, 3H), 6.71–6.74 (m, 2H), 6.88–7.20 (m, 14H), 7.27–7.32 (m, 4H), 7.48–7.55 (m, 4H), 7.62–7.65 (m, 2H), 7.85 (d, ³*J* = 15.9 Hz, 2H), 8.05 (d, ³*J* = 15.9 Hz, 1H) ppm. ¹³C NMR (75 MHz, CDCl₃): δ = 40.4, 55.5, 112.2, 112.5, 114.3, 121.9, 122.6, 123.7, 124.2, 124.7, 125.2, 126.5, 128.7, 129.2, 129.2, 129.50, 129.54, 129.8, 135.7, 136.9, 137.0, 147.4, 148.9, 151.2, 160.3, 162.7, 163.6, 164.8 ppm. IR (ATR): ν = 2925, 1561, 1490, 1247, 1170, 1144, 971, 694 cm⁻¹. HR-MALDI-MS (DCTB): *m/z* calculated for C₄₃H₃₈N₄O [M⁺] 626.3040, found 626.3038.

(*E,E,E*)-2-(4-Dimethylaminostyryl)-4-(4-methoxystyryl)-6-(4-diphenylaminostyryl)pyrimidine (5b). Synthesized from **4b** (150 mg, 0.40 mmol) and 4-*N,N*-diphenylaminobenzaldehyde (110 mg, 0.40 mmol) following the general procedure for Knoevenagel condensation. The crude product was purified by column chromatography (SiO₂, petroleum ether:EtOAc, 7:3). Yield: 84 mg (33 %); orange solid. *R*_f: 0.5 (SiO₂; petroleum ether:EtOAc, 7:3). *T*_d: 210 °C. ¹H NMR (300 MHz, CDCl₃): δ = 3.02 (s, 6H), 3.85 (s, 3H), 6.72–6.75 (m, 2H), 6.93–7.16 (m, 14H), 7.27–7.32 (m, 4H), 7.48–7.51 (m, 2H), 7.57–7.60 (m, 4H), 7.82–7.90 (m, 2H), 8.05 (d, ³*J* = 15.9 Hz, 1H) ppm. ¹³C NMR (75 MHz, CDCl₃): δ = 40.4, 55.5, 112.3, 112.3, 114.4, 122.6, 123.7, 124.2, 124.4, 124.7, 124.8, 125.2, 128.4, 128.7, 129.0, 129.2, 129.4, 129.5, 129.8, 135.9, 138.1, 147.4, 148.9, 151.0, 160.6, 162.9, 163.0, 165.4 ppm. IR (ATR): ν = 2921, 1500, 1359, 1248, 1166, 971, 809, 693 cm⁻¹. HR-MALDI-MS (DCTB): *m/z* calculated for C₄₃H₃₈N₄O [M⁺] 626.3040, found 626.3058.

(*E*)-2-Styryl-4-methylpyrimidine (6a). Synthesized from phenylacetylene (176 mg, 1.72 mmol) and 2-chloro-4-methylpyrimidine (142 mg, 1.1 mmol) following the general procedure for Suzuki-Miyaura reaction. The crude product was purified by column chromatography (SiO₂, petroleum ether:EtOAc, 8:2). Yield: 70 mg (32 %); white solid. *R*_f: 0.4 (SiO₂; petroleum ether:EtOAc, 8:2). Mp: 67.2–69.9 °C (lit.³² 65–67°C). ¹H NMR (300 MHz, CDCl₃):

1
2
3 $\delta = 2.54$ (s, 3H), 6.97 (d, $^3J = 4.8$ Hz, 1H), 7.22 (d, $^3J = 15.9$ Hz, 1H), 7.30–7.41 (m, 3H),
4
5 7.61–7.63 (m, 2H), 7.98 (d, $^3J = 15.9$ Hz, 1H), 8.56 (d, $^3J = 4.8$ Hz, 1H) ppm. ^{13}C NMR (75
6
7 MHz, CDCl_3): $\delta = 24.4, 118.3, 127.7, 128.9, 129.1, 136.3, 137.9, 156.8, 164.7, 167.1$ ppm All
8
9 the atoms of carbon were not observed. IR (ATR): $\nu = 2918, 1547, 1440, 1385, 978, 790, 747$
10
11 cm^{-1} . HR-MALDI-MS (DCTB): m/z calculated for $\text{C}_{13}\text{H}_{13}\text{N}_2$ $[(\text{M}+\text{H})^+]$ 197.1073, found
12
13 197.1073.
14
15

16 **(E)-2-(4-Methoxystyryl)-4-methylpyrimidine (6b).**

17
18 Synthesized from 4-ethynylanisole (311 mg, 2.35 mmol) and 2-chloro-4-methylpyrimidine
19
20 (193 mg, 1.50 mmol) following the general procedure for Suzuki-Miyaura reaction. The crude
21
22 product was purified by column chromatography (SiO_2 , petroleum ether:EtOAc, 7:3). Yield:
23
24 206 mg (61 %); brownish solid. R_f : 0.2 (SiO_2 ; petroleum ether:EtOAc, 7:3). Mp: 102.3–104.9
25
26 $^\circ\text{C}$. ^1H NMR (300 MHz, CDCl_3): $\delta = 2.53$ (s, 3H), 3.83 (s, 3H), 6.90–6.95 (m, 3H), 7.09 (d, 3J
27
28 $= 15.9$ Hz, 1H), 7.55–7.58 (m, 2H), 7.93 (d, $^3J = 15.9$ Hz, 1H), 8.54 (d, $^3J = 5.1$ Hz, 1H) ppm.
29
30 ^{13}C NMR (75 MHz, CDCl_3): $\delta = 24.4, 55.5, 114.4, 117.9, 125.5, 129.1, 129.2, 137.6, 156.7,$
31
32 160.6, 165.0, 167.1 ppm. IR (ATR): $\nu = 2937, 1566, 1509, 1249, 1178, 1028, 981, 821, 775$
33
34 cm^{-1} . HR-MALDI-MS (DCTB): m/z calculated for $\text{C}_{14}\text{H}_{14}\text{N}_2\text{O}$ $[\text{M}^+]$ 226.1101, found
35
36 226.1100.
37
38
39

40 **(E)-2-(4-Dimethylaminostyryl)-4-methylpyrimidine (6c).**

41
42 Synthesized from 4-ethynyl-*N,N*-dimethylaniline (250 mg, 1.72 mmol) and 2-chloro-4-
43
44 methylpyrimidine (142 mg, 1.1 mmol) following the general procedure for Suzuki-Miyaura
45
46 reaction. The crude product was purified by column chromatography (SiO_2 , petroleum
47
48 ether:EtOAc, 8:2). Yield: 85 mg (32 %); brown solid. R_f : 0.3 (SiO_2 ; petroleum ether:EtOAc,
49
50 8:2). Mp: 117.3–119.8 $^\circ\text{C}$. ^1H NMR (300 MHz, CDCl_3): $\delta = 2.51$ (s, 3H), 2.99 (s, 6H), 6.68–
51
52 6.71 (m, 2H), 6.89 (d, $^3J = 5.1$ Hz, 1H), 7.02 (d, $^3J = 15.9$ Hz, 1H), 7.49–7.52 (m, 2H), 7.92
53
54 (d, $^3J = 15.9$ Hz, 1H), 8.50 (d, $^3J = 5.1$ Hz, 1H) ppm. ^{13}C NMR (75 MHz, CDCl_3): $\delta = 24.3,$
