Running title: IE in non-IVDU pregnant women

Objectives: To describe the clinical features and outcomes of infective endocarditis (IE) in pregnant women who do not inject drugs.

Methods: A multinational retrospective study was performed at 14 hospitals. All definite IE episodes between January 2000 and April 2021 were included. The main outcomes were maternal mortality and pregnancy-related complications.

Results: Twenty-five episodes of IE were included. Median age at IE diagnosis was 33.2 years (IQR 28.3–36.6) and median gestational age was 30 weeks (IQR 16–32). Thirteen (52%) patients had no previously known heart disease. Sixteen (64%) were native IE, 7 (28%) prosthetic and 2 (8%) cardiac implantable electronic device IE. The most common aetiologies were streptococci ($n=10$, 40%), staphylococci ($n=5$, 20%), HACEK group ($n=3$, 12%) and *Enterococcus faecalis* ($n=3$, 12%). Twenty (80%) patients presented at least one IE complication; the most common were heart failure ($n=13$, 52%) and symptomatic embolism other than stroke ($n=4$, 16%). Twenty-one (84%) patients had surgery indication and surgery was performed when indicated in 19 (90%). There was one maternal death and 16 (64%) patients presented pregnancy-related complications (11 patients ≥ 1 complication): 3 pregnancy losses, 9 urgent Caesarean sections, 2 emergency Caesarean sections, 1 fetal death, and 11 preterm births. Two patients presented a relapse during a median follow-up of 3.1 years (IQR 0.6–7.4).

Conclusions: Strict medical surveillance of pregnant women with IE is required and must involve a multidisciplinary including obstetricians and neonatologists. Furthermore, the potential risk of IE during pregnancy should never be underestimated in women with previously known underlying heart disease.

Introduction

Infective endocarditis (IE) is a rare but potentially severe disease, and it is even more uncommon in pregnant women,^{1–3} with an estimated incidence of 0.00 002% among pregnant patients in a recent study.⁴ The main reported risk factors are IVDU and congenital or rheumatic cardiac diseases, but in most recent series women with IVDU are the predominant group.^{5–7} Although lower than previously reported, maternal and fetal mortality are still around 5%–11% and 0%–16%, respectively.^{3–6,8}

Contemporary clinical characteristics and prognosis of pregnant women with IE who do not inject drugs remain unknown. The aim of this study was to describe the clinical features and outcomes of a contemporary multinational cohort of IE in pregnant women who do not inject drugs.

Methods

This retrospective observational study was promoted and coordinated by Hospital Universitari Vall d'Hebron, a referral centre for IE and cardiac surgery in Barcelona, Spain. We asked 64 centres whether they had cases of IE in pregnant women between 2000 and 2021 (42 centres in France, 11 in Spain, 2 in Italy, 2 in Sweden, 2 in Denmark, 1 in Argentina, 1 in Brazil, 1 in Australia, 1 in USA and 1 in Lebanon). All of the centres answered, but only 14 centres had treated pregnant women with endocarditis (11 from France, 1 from Spain, 1 from Argentina and 1 from Brazil). All of them were centres with cardiac surgery capabilities. Only adult non-IVDU pregnant women (≥ 18 years) with definite IE according to the current Duke criteria at the time of IE diagnosis were included. IVDU was identified through medical records and women with IVDU were excluded.

A standardized case report form was designed and sent to the participating hospitals. We collected information on patient demographics, comorbidities, predisposing factors, microbiological data, ECG findings, medical and surgical treatment, pregnancy-related complications and follow-up. Variable definitions are the same as in previous studies.⁹ Main outcomes were maternal mortality and pregnancy-related complications. Pregnancy-related complications included pregnancy loss (gestational age < 24 weeks), emergency Caesarean section, fetal death (gestational age ≥ 24 weeks) and fetal morbidity (preterm birth, Apgar score < 7 , neonatal intensive care admission). Data were recorded anonymously and sent to the coordinating centre where a database was created specifically for this study.

Ethics

The study was approved by the Ethics Committee of the promoting and coordinating centre (Hospital Universitari Vall d'Hebron, PR(AG)361/2021). Informed consent from patients was not required.

Results

After excluding two cases (one due to IVDU and one because it was a postpartum IE), 25 episodes of IE in 25 pregnant patients were included in the present study. Table 1 summarizes demographic, clinical characteristics and outcomes of the 25 episodes of IE. Table S1 ([Table S1 is available as Supplementary data at JAC Online](#)) describes in detail each included patient. Median age at IE diagnosis was 33.2 years (IQR 28.3–36.6) and median gestational age at diagnosis was 30 weeks (IQR 16–32). Median Charlson Comorbidity Index was 0 (IQR 0–0). Thirteen (52%) patients had no previously known heart disease. Seven out of 12 remaining patients had prosthetic valves and three had cardiac implantable electronic devices (CIED). A detailed description of heart conditions is depicted in Table 1.

The most common symptoms were fever ($n=24$, 96%), asthenia ($n=8$, 32%) and dyspnoea ($n=6$, 24%). Sixteen (64%) patients were native valve IE, 7 (28%) were prosthetic IE and 2 (8%) were CIED IE. The mitral valve alone (10 patients, 40%) and the aortic valve alone (6 patients, 24%) were the most frequent affected.

The most common microorganisms were viridans streptococci ($n=10$, 40%), staphylococci ($n=5$, 20%), HACEK group ($n=3$, 12%) and *Enterococcus faecalis* ($n=3$, 12%).

A transthoracic ECG was performed in all patients and a transoesophageal ECG in 17 (68%). Most common echocardiographic findings were vegetations ($n=23$, 92%), new moderate or severe valvular regurgitation ($n=16$, 64%) and perivalvular abscess ($n=4$, 16%). A previously unknown heart disease was diagnosed in two patients (a bicuspid aortic valve and a mitral valve prolapse).

Twenty (80%) patients presented at least one IE complication. The most common complications were heart failure ($n=13$, 52%) and symptomatic embolism other than stroke ($n=4$, 16%). Twenty-one (84%) patients had surgical indication according to current ESC guidelines and surgery was performed when indicated in 19 (90%) of those patients. In one case, surgery was not performed due to a high risk for the fetus (in this woman the indication was prevention of embolism) and in another one due to a surgical procedure that was presumed difficult (IE on a CIED implanted 15 years before).

There was one maternal death that occurred during surgery. Sixteen (64%) patients presented pregnancy-related complications, including 11 with more than one

complication. There were 3 pregnancy losses (2 in the first trimester of pregnancy and 1 in the second), 9 emergency Caesarean sections and 2 urgent Caesarean sections (9 Caesarean sections were performed prior surgery), 1 fetal death and 11 preterm births (2 required neonatal intensive care admission).

Median hospital stay was 32.5 (IQR 24–41.5) days and median follow-up duration after hospital discharge was 3.1 (IQR 0.6–7.4) years. Two patients presented a relapse during follow-up (one patient with *Staphylococcus aureus* CIED IE who was not operated despite surgical indication relapsed at 27 days after antibiotic treatment discontinuation, and one patient with streptococcal prosthetic IE without surgical indication initially relapsed at Day 7 after antimicrobial treatment discontinuation): both had favourable outcomes with a new course of antibiotic treatment and cardiac surgery. Two other patients also required valve surgery during follow-up (one 14 months after valvuloplasty due to recurrence of severe mitral regurgitation and the other 10 years after bioprosthesis implantation due to prosthesis degeneration).

Discussion

This multinational retrospective study demonstrates that: (i) IE in non-IVDU pregnant women is very uncommon, as only 14 out of 64 hospitals had a case, with only 25 cases collected over 21 years; (ii) IE in non-IVDU pregnant patients usually affects women with previous heart disease, sometimes undiagnosed before IE; (iii) the most common responsible microorganisms are the same as for non-pregnant patients;¹ and (iv) IE complications occur in most cases and frequently require surgery with a high rate of pregnancy-related complications.

Previous studies focused on IE in pregnant women with IVDU,⁵⁻⁷ and found that the most common aetiology was staphylococci, with a predominance of right-sided IE, and no need for surgical treatment in most cases.^{5,6} In the study reported herein, we found mostly left-sided IE, with streptococcal predominance and a high rate of cardiac surgery, probably related to the fact that IVDU women were excluded.

In comparison with cases included in the recent ESC-EORP EURO-ENDO registry, in our study there was a lower proportion of acute renal failure (4% versus 17.7%), but a higher rate of heart failure (52% versus 14.1%).¹⁰ This may be related, respectively, to the younger age and morbidity of the patients, and to the cardiovascular and haemodynamic changes related to pregnancy that may favour heart failure.

Cardiac surgery and cardiopulmonary bypass are associated with significant fetus and mother mortality.¹¹ In our series, Caesarean section was performed in nine cases prior surgery. Only one woman died, during surgery, with fetal loss. Two other fetal losses occurred at 3 and 4 days after surgery, respectively, confirming the high risk of cardiac surgery during pregnancy and suggesting that may be Caesarean section or vaginal delivery should be performed whenever possible prior to valve surgery.

Maternal mortality has decreased in comparison to old series,^{5,6} probably due to a higher prevalence of IVDU patients who are usually younger and have right-sided IE, both being associated with a better prognosis. However, in our series that does not include IVDU patients, maternal mortality is also lower. A recent national cohort study from the USA found that IE during pregnancy was not associated with additional risks for adverse outcome when compared with IE in non-pregnant women.⁴ Unfortunately, the absence of a control group of non-pregnant women with IE in the same age range does not allow us to verify this data in our cohort. In the US study, pregnant women

with IE had worse maternal and fetal outcomes than pregnant women without IE,⁴ in line with the high fetal mortality observed in our cohort.

This study has several limitations, such as the small sample size, the possible variability of patient management between centres and the absence of a control group. In addition, our method of case ascertainment is limited by provider recollection and provider presence at that facility over the entire study period. Finally, the retrospective nature of the study does not allow us to assess if obstetric complications are related to the maternal condition. However, the multicentre nature of the study is a remarkable strength. Furthermore, although IE in pregnant woman is a very rare disease and pregnancy is a variable absent in many databases, most investigators in this field remember these patients due to the associated high emotional impact.

In conclusion, in our series IE in pregnant patients who do not use intravenous drugs is frequently associated with IE complications, requires cardiac surgery in most of the cases and is associated with high fetal mortality. Therefore, strict medical surveillance of pregnant women with IE is required and must involve a multidisciplinary team, including not only cardiologists, surgeons and infectious diseases specialists with expertise in IE but also obstetricians and neonatologists, in order to improve both maternal and fetal prognosis. Furthermore, the potential risk of IE during pregnancy should never be underestimated in women with previously known underlying heart disease. These patients should receive prophylactic antibiotics when indicated, and blood cultures should be early performed in case of unexplained fever.
