#### Abstract

Tricarbon and pentacarbon monoxides have been detected towards TMC-1 with relatively important abundances. Understanding their chemical formation of these molecules requires interpreting their observational spectra by mean of non-local thermodynamical equilibrium modelling. For this purpose, we report rate coefficients of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ induced by collision with He for temperatures up to 100 K . These data are obtained by calculating inelastic cross sections for the 31 low-lying rotational levels of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ using the close-coupling approach. The comparison of the new rate coefficients with those of $\mathrm{HC}_{3} \mathrm{~N}$ and $\mathrm{HC}_{5} \mathrm{~N}$, previously used to interpret the observational spectra of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$, reveals differences of up to an order of magnitude. The effect of the new collisional rate coefficients in radiative transfer calculations is checked by computing the excitation temperatures for some transitions and simulating the $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ column densities observed towards TMC-1. Our findings suggest that the use of $\mathrm{HC}_{n} \mathrm{~N}$ as template for $\mathrm{C}_{n} \mathrm{O}$ may lead to local thermodynamic equilibrium conditions for gas densities as low as $\sim 10^{3} \mathrm{~cm}^{-3}$. Regarding the interpretation of the observational spectra, using radiative transfer modelling based on the actual $\mathrm{C}_{n} \mathrm{O}$ collisional rate coefficients instead of rotational diagram analysis leads to underestimate the column densities reported in the literature by up to $25 \%$ and accordingly the $\mathrm{C}_{3} \mathrm{O} / \mathrm{C}_{5} \mathrm{O}$ abundance ratio by up to $50 \%$. We expect that the new rate coefficients and the radiative transfer calculations presented in this work will encourage further modellings of the $\mathrm{C}_{n} \mathrm{O}$ abundance and accordingly constrain the chemistry.

Key words: ISM: molecules - molecular data - scattering

## 1 INTRODUCTION

During the last decades, important theoretical and experimental progresses were made to determine high accurate molecular spectroscopic data such as electric dipole moment and rotational constant. These pieces of information are crucial to identify interstellar molecules through their observational spectra. For instance, the detection of $l-\mathrm{HC}_{3}^{+}$towards the Horsehead nebula (Pety et al. 2012) was questioned by ab initio calculations (Huang et al. 2013) then confirmed by laboratory measurements (Brünken et al. 2014).
Thanks to these efforts, TMC-1 is now known as an astronomical source particularly rich of carbon chain molecules such as $\mathrm{C}_{n} \mathrm{~N}$ (Friberg et al. 1980; Guélin et al. 1998), $\mathrm{C}_{n} \mathrm{~S}$ (Cernicharo et al. 2021a) and especially $\mathrm{C}_{n} \mathrm{O}(n \geq 3)$ whose chemical growth remains to be understood. $\mathrm{C}_{3} \mathrm{O}$ was first detected by Matthews et al. (1984) through its $2 \rightarrow 1$ rotational emission line towards TMC-1, then Brown et al. (1985) detected the $5 \rightarrow 4,8 \rightarrow 7$ and $9 \rightarrow 8$ lines in the same region. Furthermore, this molecule was identified towards different astronomical sources, namely the carbon rich circumstellar envelope IRC +10216 (Tenenbaum et al. 2006), the low-mass protostar ELIAS 18 (Palumbo et al. 2008) and the prestellar core L1544 (Vastel et al.

[^0]2014). Recently, Cernicharo et al. (2021b) reported the discovery of $\mathrm{C}_{5} \mathrm{O}$ in TMC-1. These authors detected 6 emission lines involving only high-lying rotational energy levels, i.e. $j=12-17 \rightarrow 11-16$. Therefore, highly accurate determination of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ abundances can lead to a better understanding of the $\mathrm{C}_{n} \mathrm{O}$ chemistry in TMC-1.

The column densities of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ observed towards TMC1 were determined by mean of rotational diagram analysis of the observational spectra (Cernicharo et al. 2021b), i.e. by assuming that local thermodynamic equilibrium (LTE) conditions are reached. The use of such an approximation is motivated by the lack of collisonal data for $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ even though LTE conditions are rarely verified in the ISM. To check the validity of their assumption, Cernicharo et al. (2021b) calculated excitation temperatures for the observed lines under the large velocity gradient (LVG) approach adopting collisional rate coefficients of $\mathrm{HC}_{3} \mathrm{~N}$ and $\mathrm{HC}_{5} \mathrm{~N}$ as template for $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$, respectively. Despite the similarity of the $\mathrm{C}_{n} \mathrm{O}$ and $\mathrm{HC}_{n} \mathrm{~N}$ electronic structures, the impact of the actual $\mathrm{C}_{n} \mathrm{O}$ collisional rate coefficients in the abundance determination deserves to be assessed.

Collisional excitation of CO , the simplest member of the $\mathrm{C}_{n} \mathrm{O}$ family, by He has been extensively investigated both theoretically and experimentally. For example, using a potential energy surface (PES) based on the electron-gas model, Green \& Thaddeus (1976) calculated collisional rate coefficients up to 100 K for the low-lying
rotational energy levels of $\mathrm{CO}-\mathrm{He}$ and $\mathrm{CO}-\mathrm{H}_{2}$. Subsequently, using a high accurate ab initio potential computed by Heijmen et al. (1997), Cecchi-Pestellini et al. (2002) reported CO rate coefficients due to collision with He for temperatures up to 500 K . Nevertheless, $\mathrm{C}_{3} \mathrm{O}$ received less attention despite its early discovery towards TMC-1 (Matthews et al. 1984).

Collisional excitation of $\mathrm{C}_{3} \mathrm{O}$ (Khadri \& Hammami 2019) and $\mathrm{C}_{5} \mathrm{O}$ (Khadri et al. 2022) by He was studied recently by mean of state-of-the-art methods. New 2D-PESs were calculated using high accurate $a b$ initio level of theories. Based on the latter data, collisional rate coefficients for the 12 (20) low-lying rotational levels of $\mathrm{C}_{3} \mathrm{O}-\mathrm{He}$ ( $\mathrm{C}_{5} \mathrm{O}-\mathrm{He}$ ) were derived for temperatures up to $25 \mathrm{~K}(100 \mathrm{~K})$. Since $\mathrm{C}_{3} \mathrm{O}$ and especially $\mathrm{C}_{5} \mathrm{O}$ were detected through rotational emission lines involving high-lying energy levels (up to $11 \rightarrow 10$ for $\mathrm{C}_{3} \mathrm{O}$ and $17 \rightarrow 16$ for $\mathrm{C}_{5} \mathrm{O}$ ) we revisit the excitation of these molecules induced by collision with He to provide a complete set of data. In fact, modelling the $11 \rightarrow 10$ (for $\mathrm{C}_{3} \mathrm{O}$ ) and $17 \rightarrow 16$ (for $\mathrm{C}_{5} \mathrm{O}$ ) requires accounting for contributions from populations of rotational levels as high as 20 and 30 , respectively.

The use of He as collision partner is usual in the literature since it provides rough estimates for para- $\mathrm{H}_{2}\left(j_{2}{ }^{1}=0\right)$, i.e. the most abundant species in the ISM and especially in TMC-1 where $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ were observed. Both projectiles are closed-shell, spherical and two-valence-electron species. Therefore, rate coefficients induced by collision with He can be multiplied by the mass scaling factor to roughly estimate those due to para $-\mathrm{H}_{2}\left(j_{2}=0\right)$ impact. Indeed, Wernli et al. (2007) showed an average ratio of $\sim 1.4$ between the $\mathrm{HC}_{3} \mathrm{~N}-$ para $-\mathrm{H}_{2}\left(\mathrm{j}_{2}=0\right)$ and $\mathrm{HC}_{3} \mathrm{~N}-\mathrm{He}$ collisional rate coefficients. This finding for an $\mathrm{HC}_{n} \mathrm{~N}$-type molecule, let us expect a reasonably good agreement in the case of $\mathrm{C}_{n} \mathrm{O}$, i.e the isoelectronic compounds. However, we anticipate by warning that this approximation is limited especially for charged species and hydrides.

This paper is structured as follows: Section 2 presents the computational details, in Section 3 we discus the results and Section 4 gives the concluding remarks

## 2 METHODS

### 2.1 Analytical fit

The data reported in this work are calculated using the potential energy surfaces (PESs) of the $\mathrm{C}_{3} \mathrm{O}-\mathrm{He}$ and $\mathrm{C}_{5} \mathrm{O}-\mathrm{He}$ complexes (Khadri \& Hammami 2019; Khadri et al. 2022). Briefly, the PESs are calculated at the $\operatorname{CCSD}(\mathrm{T})-\mathrm{F} 12^{2} /$ aug-cc-pVTZ ${ }^{3}$ level of theory using the rigid-rotor approximation. Since the electronic calculations are out of the scope of this work, we refer the readers to the papers mentioned above.

To obtain collisional rate coefficients for higher rotational levels of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$, we determine new analytical fits of the ab initio potentials including few radial terms $\left(V_{\lambda}\right)$ to keep the computational time reasonably low. In fact, due to the rod-like shape of the $\mathrm{C}_{n} \mathrm{O}$ molecules, Khadri \& Hammami (2019) and Khadri et al. (2022) used 77 and 72 terms to reproduce reasonably well the ab initio PESs of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$, respectively. To reduce the number of radial terms without losing precision on the analytical potentials, we used

[^1]Table 1. State-to-state inelastic cross sections (in unit of $\AA^{2}$ ) of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ computed at $100 \mathrm{~cm}^{-1}$ using the old ${ }^{(a, b)}$ and new analytical PESs.

the weighted least square multiple regression method (Filliben \& Heckert 2002) in the expansion of the ab initio PESs over Legendre polynomials:
$V(R, \theta)=\sum_{\lambda=0}^{\lambda_{\text {max }}} V_{\lambda}(R) P_{\lambda}(\cos \theta)$,
where R is the distance between the centers of mass of the monomers (i.e. $\mathrm{C}_{n} \mathrm{O}$ and He ) and $\theta$ stands for the scattering angle. This approach yields 35 and 27 radial coefficients for the PESs of $\mathrm{C}_{3} \mathrm{O}-\mathrm{He}$ and $\mathrm{C}_{5} \mathrm{O}-\mathrm{He}$, respectively. The so-obtained analytical potentials are shown in Fig. 1, they are identical to the interpolated ab initio PESs represented in the works of Khadri \& Hammami (2019) and Khadri et al. (2022). It is worth noting that in this representation the linear configurations $\mathrm{He} \cdots \mathrm{C}_{n} \mathrm{O}$ and $\mathrm{C}_{n} \mathrm{O} \cdots$ He correspond to $\theta=0^{\circ}$ and $\theta=180^{\circ}$, respectively. Both potentials (especially in the case of $\mathrm{C}_{5} \mathrm{O}-\mathrm{He}$ ) are very anisotropic and manifest a stronger repulsion towards the carbon-end (i.e. $\theta=0^{\circ}$ ) and present shallow minima. Indeed, the $\mathrm{C}_{5} \mathrm{O}-\mathrm{He}$ PES exhibits two minima of $59.3 \mathrm{~cm}^{-1}$ and 53.06 $\mathrm{cm}^{-1}$ which are similar in magnitude to the unique global minimum of $53.4 \mathrm{~cm}^{-1}$ obtained for $\mathrm{C}_{3} \mathrm{O}-\mathrm{He}$. Moreover, in $\mathrm{C}_{n} \mathrm{O}-\mathrm{He}(n=3,5)$ systems and unlike their $\mathrm{C}_{n} \mathrm{~S}-\mathrm{He}$ valence isoelectronic counterparts (Sahnoun et al. 2020; Khadri et al. 2020), the charge distribution on the oxygen atom is negative and the Pauli exchange repulsion does not allow quasi-bonding between the O and He atoms. To check the validity of our new fit, we compare in Table 1 state-to-state inelastic cross-sections of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ computed using the old (Khadri \& Hammami 2019; Khadri et al. 2022) and new (this work) analytical PESs. For all transitions, slight deviations (less than $2 \%$ ) are orbserved.

### 2.2 Cross sections and rate coefficients

The collisional processes we are studying can be sketched as follows:

$$
\begin{equation*}
\mathrm{C}_{n} \mathrm{O}(j)+\mathrm{He} \rightarrow \mathrm{C}_{n} \mathrm{O}\left(j^{\prime}\right)+\mathrm{He} \tag{2}
\end{equation*}
$$

where $n=\{3,5\}$ and $j$ being the total angular momentum of $\mathrm{C}_{n} \mathrm{O}$. We report state-to-state inelastic cross sections $(\sigma)$ for the 31 lowlying rotational levels of $\mathrm{C}_{n} \mathrm{O}(j=0-30)$. Calculations are performed for total energies ranging up to $750 \mathrm{~cm}^{-1}$ and $650 \mathrm{~cm}^{-1}$ for $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$, respectively. To correctly describe the resonances, we span the energy range using a fine step size of $0.1 \mathrm{~cm}^{-1}$ up to $200 \mathrm{~cm}^{-1}\left(100 \mathrm{~cm}^{-1}\right)$ for $\mathrm{C}_{3} \mathrm{O}\left(\mathrm{C}_{5} \mathrm{O}\right)$. The calculations are performed by mean of the quantum mechanical close-coupling approach as implemented in the MOLSCAT computer code (Alexander 1977; Hutson \& Green code).

Convergence tests are performed at the first stage to determine the integration parameters (see Table 2) which are $j_{\max }$ (the size of the rotational basis), STEPS (a parameter inversely proportional to the integration step) and $R_{\text {mid }}$ (the switching point between the short and the long-range of the integration length).

Using a thermal average over the Maxwell-Boltzmann kinetic energy $\left(E_{k}\right)$ distribution of the so-calculated cross sections, we retrieve

Figure 1. Contour plots of the $\mathrm{C}_{3} \mathrm{O}-\mathrm{He}$ (upper panel) and $\mathrm{C}_{5} \mathrm{O}-\mathrm{He}$ (lower panel) 2D interaction potentials (in $\mathrm{cm}^{-1}$ ). The $\mathrm{C}_{n} \mathrm{O}$ molecules are shown to scale and the bond distances are in $\AA$.
collisional rate coefficients $(k)$ of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ for temperatures up to 100 K ,
$k_{j \rightarrow j^{\prime}}(T)=\left(\frac{8}{\pi \mu \beta}\right)^{1 / 2} \beta^{2} \int_{0}^{\infty} E_{k} \sigma_{j \rightarrow j^{\prime}}\left(E_{k}\right) e^{-\beta E_{k}} d E_{k}$
where $\mu$ is the reduced mass of $\mathrm{C}_{n} \mathrm{O}-\mathrm{He}$ and $\beta=\left(k_{B} T\right)^{-1}$ is inversely proportional to the Boltzmann constant and the temperature.

### 2.3 Radiative transfer study

Radiative transfer calculations are performed under the escape probability formalism, as implemented in the RADEX computer code

Table 2. Integration parameters used in the dynamic calculations

|  | $j_{\text {max }}$ | STEPS | $R_{\text {mid }}$ |
| :---: | :---: | :---: | :---: |
| $\mathrm{C}_{3} \mathrm{O}$ | $14-37$ | $10-80$ | $15 a_{0}$ |
| $\mathrm{C}_{5} \mathrm{O}$ | $22-49$ | $10-80$ | $14 a_{0}$ |

Figure 2. Comparison between collisional rate coefficients $\left(\mathrm{cm}^{3} \mathrm{~s}^{-1}\right)$ of $\mathrm{C}_{3} \mathrm{O}-\mathrm{He}$ and those of $\mathrm{C}_{5} \mathrm{O}-\mathrm{He}$ for a temperature of 10 K . The solid diagonal line stands for $y=x$ and the dashed lines delimit an agreement of a factor of 2.
(Van der Tak et al. 2007), assuming an expanding spherical shell. The basic input consists of collision rate coefficients, line frequencies, energy levels and Einstein coefficients for both $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$. The spectroscopic data are downloaded from the Cologne Database for Molecular Spectroscopy (CDMS) portal (Endres et al. 2016).

In this section, we calculate excitation temperature ( $T_{\mathrm{ex}}$ ), brightness temperature $\left(T_{\mathrm{B}}\right)$, integrated intensity $(W)$ and optical depth $(\tau)$ for the detected emission lines of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ and towards TMC-1 (Matthews et al. 1984; Brown et al. 1985; Cernicharo et al. 2021b). The cosmic microwave background temperature ( $T_{\mathrm{CMB}}=2.73 \mathrm{~K}$ ) is used as background radiation field. For the full width at the halfmaximum (FWHM), we use the values reported in the literature. We report in Table 3 a brief summary of the parameters of the observed emission lines including the antenna temperature $\left(T_{A}^{*}\right)$ and the integrated intensity. Concerning physical conditions of the source of interest, i.e. TMC-1, the $\mathrm{H}_{2}$ volume density $(n)$ is smoothly increased from $10^{2} \mathrm{~cm}^{-3}$ to $10^{8} \mathrm{~cm}^{-3}$ and the gas kinetic temperature $(T)$ is set to $10 \pm 2 \mathrm{~K}$ as usually done in the literature (Ndaw et al. 2021; Bop et al. 2021). The column densities ( $N$ ) of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ are smoothly increased from $10^{10} \mathrm{~cm}^{-2}$ to $10^{13} \mathrm{~cm}^{-2}$ and $10^{9} \mathrm{~cm}^{-2}$ to $10^{12} \mathrm{~cm}^{-2}$, respectively.

## 3 RESULTS

### 3.1 Collisional excitation of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$

Fig. 2 compares rate coefficients of $\mathrm{C}_{3} \mathrm{O}$ induced by collision with He to those of $\mathrm{C}_{5} \mathrm{O}$ for a temperature of 10 K which corresponds to the gas kinetic temperature of TMC-1. Apart from the most dominant transitions (i.e. $\Delta j=1$ and $k \sim 10^{-10} \mathrm{~cm}^{3} \mathrm{~s}^{-1}$ ), the scattering of $\mathrm{C}_{5} \mathrm{O}$ outweighs that of $\mathrm{C}_{3} \mathrm{O}$. The disagreement increases up to an order of magnitude with the increase of $\Delta j$ (see appendix A fore the

Table 3. Emission line parameters of the $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ observed towards TMC-1.

behaviour of the state-to-state rate coefficients). Similar behaviour is expected between $\mathrm{HC}_{3} \mathrm{~N}$ and $\mathrm{HC}_{5} \mathrm{~N}$ since their collisional data were used to interpret the emission lines of $\mathrm{C}_{3} \mathrm{O}$ (Brown et al. 1985) and $\mathrm{C}_{5} \mathrm{O}$ (Cernicharo et al. 2021b) detected towards TMC-1, respectively. Let us notice that the rate coefficients of $\mathrm{HC}_{3} \mathrm{~N}$ were reported by Green \& Chapman (1978); Wernli et al. (2007) and those of $\mathrm{HC}_{5} \mathrm{~N}$ were determined using the extrapolation method suggested by Snell et al. (1981).
$k_{\mathrm{HC}_{5} \mathrm{~N}-\mathrm{H}_{2}}(T)=k_{\mathrm{HC}_{3} \mathrm{~N}-\mathrm{H}_{2}}(T) \times\left(\frac{1}{2}+\frac{1}{2} \frac{k_{\mathrm{HC}_{3} \mathrm{~N}-\mathrm{H}_{2}}(T)}{k_{\mathrm{HCN}-\mathrm{H}_{2}}(T)}\right)$
For both HCN (Hernández Vera et al. 2017) and $\mathrm{HC}_{3} \mathrm{~N}$ (Wernli et al. 2007) we use the rate coefficients induced by collision with para $-\mathrm{H}_{2}\left(j_{2}{ }^{4}=0\right)$.

We display in Fig. 3 the dependence on $j^{\prime}$ of rate coefficients of $\mathrm{C}_{3} \mathrm{O}, \mathrm{HC}_{3} \mathrm{~N}, \mathrm{C}_{5} \mathrm{O}$ and $\mathrm{HC}_{5} \mathrm{~N}$ induced by collision with $\mathrm{He} / \mathrm{H}_{2}$. As one can see, the excitation of $\mathrm{HC}_{n} \mathrm{~N}$ is much stronger than that of $\mathrm{C}_{n} \mathrm{O}$. Typically, the disagreement increases with the increment of $\Delta j$. For example, the data of Wernli et al. (2007) [Green \& Chapman (1978)] for $\mathrm{HC}_{3} \mathrm{~N}-\mathrm{He}$ differ to those of $\mathrm{C}_{3} \mathrm{O}-\mathrm{He}$ computed in this work by up to two [one] orders of magnitude. The same behaviour is observed between the rate coefficients of $\mathrm{C}_{5} \mathrm{O}-\mathrm{He}$ (calculated in this work and multiplied by a mass scaling factor of $\sim 1.38$ ) and those of $\mathrm{HC}_{5} \mathrm{~N}-\mathrm{H}_{2}$ (obtained using equation 4). However, the use of $\mathrm{HC}_{5} \mathrm{~N}$ as substitute for $\mathrm{C}_{5} \mathrm{O}$ leads to a larger overestimation than the use of $\mathrm{HC}_{3} \mathrm{~N}$ as template for $\mathrm{C}_{3} \mathrm{O}$. For example, the collisional rate coefficients of $\mathrm{C}_{3} \mathrm{O}$ and those of $\mathrm{HC}_{3} \mathrm{~N}$ (Green \& Chapman 1978) satisfy the same propensity rule, i.e. in favor of odd $\Delta j$ transitions. On the other hand, the data of $\mathrm{HC}_{3} \mathrm{~N}$ (Wernli et al. 2007) $\left[\mathrm{HC}_{5} \mathrm{~N}\right.$ (equation 4)] display a propensity rule in favor of even [odd] $\Delta j$ transitions whereas $\mathrm{C}_{3} \mathrm{O}\left(\mathrm{C}_{5} \mathrm{O}\right)$ favorites odd [even] $\Delta j$ transitions which leads to much larger differences. In summary, the use of $\mathrm{HC}_{3} \mathrm{~N}$ $\left(\mathrm{HC}_{5} \mathrm{~N}\right)$ as template for $\mathrm{C}_{3} \mathrm{O}\left(\mathrm{C}_{5} \mathrm{O}\right)$ is expected to alter the analysis of the observational spectra and accordingly the abundance ratio between $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$.

### 3.2 The impact of collisional rate coefficients in non-LTE modelling

To assess the effect of the new collisional rate coefficients in nonLTE radiative transfer modelling, we use the spectroscopic data of $\mathrm{C}_{3} \mathrm{O}\left(\mathrm{C}_{5} \mathrm{O}\right)$ along with the rate coefficients of $\mathrm{HC}_{3} \mathrm{~N}\left(\mathrm{HC}_{5} \mathrm{~N}\right)$ on one hand and we couple the spectroscopic data mentioned above with the actual $\mathrm{C}_{3} \mathrm{O}\left(\mathrm{C}_{5} \mathrm{O}\right)$ rate coefficients on the other hand. These two approaches are denoted thereafter as Model (1G/W/E) and Model (2), respectively. The letter "G" ["W"] refers to collisional

[^2]rate coefficients computed by Green \& Chapman (1978) [Wernli et al. (2007)] and " E " stands for equation 4, respectively.
$\mathbf{C}_{3} \mathbf{O}$ : We compare in Fig. 4 excitation temperature of $\mathrm{C}_{3} \mathrm{O}$ computed using Model (1G/W) and Model (2). For all emission lines, Model ( $1 \mathrm{G} / \mathrm{W}$ ) leads to greater $T_{\mathrm{ex}}$ values than Model (2) except at low and high $\mathrm{H}_{2}$ volume densities where we observe excellent agreements. For the $2 \rightarrow 1$ line, Model (1G) produces a suprathermal excitation at [ $2 \times 10^{3}-4 \times 10^{4}$ ] $\mathrm{cm}^{-3}$, i.e. typical gas density of molecular clouds such as TMC-1, leading to an overestimation of a factor of $\sim 2$ with respect to Model (2).

On the other hand, the agreement obtained between the two models at low and high densities can be explained calling back the fact that the radiation field and Einstein coefficients are the same in both models. In fact, at low (high) density the molecular cloud is diffuse (dense) and the $\mathrm{C}_{3} \mathrm{O}$ excitation is dominated by the background radiation field (Einstein coefficients).

In the intermediary region, i.e. $10^{3} \leq n\left(\mathrm{~cm}^{-3}\right) \leq 10^{6}$, the dominance of Model (1W) over Model (1G) and Model (2) can be directly related to the preponderance of $k_{\mathrm{HC}_{3} \mathrm{~N}}$ (Wernli et al. 2007) over $k_{\mathrm{HC}_{3} \mathrm{~N}}$ (Green \& Chapman 1978) and $k_{\mathrm{C}_{3} \mathrm{O}}$ (see Fig. 3).

Concerning the thermalisation of the emission lines, Model ( $1 \mathrm{G} / \mathrm{W}$ ) suggests that LTE is reached at densities lower than predicted by Model (2). This behaviour is a further evidence of the overestimation of the $\mathrm{C}_{3} \mathrm{O}$ collisional rate coefficients due to the use of $\mathrm{HC}_{3} \mathrm{~N}$ as template in Model $(1 \mathrm{G} / \mathrm{W})$. Apart from the $2 \rightarrow 1$ emission line, which is much higher due to the suprathermal effect, Model (1W) (Model (1G)) [Model (2)] predicts excitation temperatures of $5-10 \mathrm{~K}(5-9 \mathrm{~K})[3-7 \mathrm{~K}]$ for volume densities of [1 $-4] \times 10^{4} \mathrm{~cm}^{-2}$, i.e. typical conditions for TMC-1. Indeed, considering a density of $4 \times 10^{4} \mathrm{~cm}^{-2}$, Cernicharo et al. (2021b) obtained excitation temperatures of $\sim 10 \mathrm{~K}$ for the $\mathrm{C}_{3} \mathrm{O}$ transitions involving low-lying energy levels ( $j \leq 5$ ). These authors used Large Velocity Gradient (LVG) model adopting the $\mathrm{HC}_{3} \mathrm{~N}-\mathrm{H}_{2}$ collisional rate coefficients as template for $\mathrm{C}_{3} \mathrm{O}-\mathrm{H}_{2}$ to check the assumption (the $\mathrm{C}_{3} \mathrm{O}$ rotational temperature is uniform for all rotational levels) made in the analysis of the observational spectra. Let us notice that when LTE is reached, $T_{\text {ex }}$ approaches asymptotically the gas kinetic temperature which is in these calculations 10 K . Therefore, assuming LTE conditions to interpret the emission lines of $\mathrm{C}_{3} \mathrm{O}$ detected towards TMC-1 would lead to overestimate the excitation temperature by up to a factor of 3 .

We plot also in Fig. 4 the opacity of the lines as a function of the gas volume density. As one can see, the optical depth is less than 0.1 for all emission lines which corroborates the validity of the optically thin regime. Seen that the opacity is proportional to the column density, the lines remain thin even for $N=10^{13} \mathrm{~cm}^{-2}$.

Figure 3. Comparison of collisional rate coefficients computed for temperature of $10 \mathrm{~K}: k_{\mathrm{C}_{3} \mathrm{O}--\mathrm{He}}$ and $1.38 \times k_{\mathrm{C}_{5} \mathrm{O}--\mathrm{He}}$ versus $\mathrm{HC}{ }_{3} \mathrm{~N}-\mathrm{He}$ and $\mathrm{HC}_{5} \mathrm{~N}-\mathrm{H}_{2}$, respectively. Superscripts ${ }^{(a)}$ and ${ }^{(b)}$ refer to Green \& Chapman (1978) and Wernli et al. (2007), respectively whereas ${ }^{(c)}$ stands for extrapolation obtained using equation 4

Figure 4. Dependence on volume density of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ excitation temperatures. The data are computed using Model (1W) (red solid lines), Model (1G) (orange solid lines), Model (1E) (red solid line) and Model (2) (green solid line). The blue dashed lines represent the opacity calculated using Model (2) but scaled up by factors of $100\left(\mathrm{C}_{3} \mathrm{O}\right)$ and $1000\left(\mathrm{C}_{5} \mathrm{O}\right)$ for clarity reasons. The emission lines are shown in the panels. For $\mathrm{C}_{3} \mathrm{O}\left(\mathrm{C}_{5} \mathrm{O}\right), T$ and $N$ are set to 10 K and $10^{12} \mathrm{~cm}^{-2}\left(10 \mathrm{~K}\right.$ and $10^{11} \mathrm{~cm}^{-2}$ ), respectively.
$\mathbf{C}_{5} \mathbf{O}$ : In this section, we briefly discuss the use of Model (1E) instead of Model (2) to interpret the $\mathrm{C}_{5} \mathrm{O}$ emission lines. The comparison between the models does not change much depending on the molecule.

Only the $12 \rightarrow 11$ and $13 \rightarrow 12$ lines are shown in Fig. 4 since the behaviour is the same for transitions involving upper energy levels $(j=14-17)$. The $\mathrm{HC}_{5} \mathrm{~N}-\mathrm{H}_{2}$ rate coefficients are so large that $T_{\text {ex }}$ computed with Model (1E) is much greater than $T_{\mathrm{CMB}}$ at $n=10^{2} \mathrm{~cm}^{-3}$. In addition, this model predicts thermalization for $n \leq 10^{4} \mathrm{~cm}^{-3}$ for all lines whereas Model (2), which uses the actual rate coefficients of $\mathrm{C}_{5} \mathrm{O}$, indicates that LTE is reached only
for $n \geq 10^{6} \mathrm{~cm}^{-3}$. For example, for a density of $[1-4] \times 10^{4} \mathrm{~cm}^{-3}$, Model (1E) and Model (2) lead to excitation temperatures of $\sim 10 \mathrm{~K}$ and [5-7] K, respectively. Indeed, to check the validity of the rotational diagram analysis, Cernicharo et al. (2021b) obtained $T_{\mathrm{ex}}$ of [9.5-10.0] K. The latter authors used LVG calculations along with the $\mathrm{HC}_{5} \mathrm{~N}$ rate coefficients (i.e. a model which is similar to Model (1E)) adopting a density of $4 \times 10^{4} \mathrm{~cm}^{-3}$ and a kinetic temperature of 10 K . Therefore, the use Model (1E) validates the rotational diagram analysis whereas Model (2) strongly suggests non-LTE modelling.

Figure 5. Dependence on $\mathrm{H}_{2}$ volume density and $\mathrm{C}_{3} \mathrm{O}\left(\mathrm{C}_{5} \mathrm{O}\right)$ column density of the $\chi^{2}$-parameter for a kinetic temperature of $10 \pm 2 \mathrm{~K}$. The contour plots, from the inner to the outer, represent confidence levels of $20 \%, 68 \%, 90 \%$ and $99 \%$. The shaded area show the typical gas density of TMC-1. The letters "w" and "e" stand for Model (1W) and Model (1E) respectively.

### 3.3 Interpretation of the $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ observational spectra

We do not claim to interpret the observational spectra of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ using the most rigorous model but to assess the impact of the new rate coefficients in the $N\left(\mathrm{C}_{3} \mathrm{O}\right) / N\left(\mathrm{C}_{5} \mathrm{O}\right)$ abundance ratio. Therefore, we assume for all emission lines that the source fills the beam. We consider the main beam brightness temperature as being the antenna temperature. Ignoring the filling factor and the telescope beam and forward efficiencies does not affect our analysis since we proceed the same way for both models [Model (1E/W) and Model (2)].

We use the parameters described in Sec. 2.3 to reproduce the integrated intensities of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ reported by Cernicharo et al. (2021b), see Table 3. In practice, the $\mathrm{H}_{2}$ volume density and the $\mathrm{C}_{3} \mathrm{O}$ $\left(\mathrm{C}_{5} \mathrm{O}\right)$ column density that best fit the observations are determined
by minimizing the $\chi^{2}$-parameter ${ }^{5}$ computed as follows:

$$
\begin{equation*}
\chi^{2}=\sum_{i=1}^{n}\left(\frac{W_{i}^{o b s}-W_{i}^{c a l}}{\sigma_{i}}\right)^{2} . \tag{5}
\end{equation*}
$$

We show in Fig. 5 the dependence on $\mathrm{H}_{2}$ volume density and $\mathrm{C}_{3} \mathrm{O}$ $\left(\mathrm{C}_{5} \mathrm{O}\right)$ column density of the $\chi^{2}$-parameter for a kinetic temperature of $10 \pm 2 \mathrm{~K}$. For both models, few $\mathrm{C}_{3} \mathrm{O}\left(\mathrm{C}_{5} \mathrm{O}\right)$ column density values allow to reproduce the observations with confidences better than $20 \%$ and $68 \%$. In addition, both models predict very similar column densities. For example, within a confidence of $20 \%$ the models suggest $N=[4.0-9.5] \times 10^{11} \mathrm{~cm}^{-2}$ for $\mathrm{C}_{3} \mathrm{O}$ and $N=[0.8-1.0] \times 10^{10} \mathrm{~cm}^{-2}$ for $\mathrm{C}_{5} \mathrm{O}$. It is worth noting that these column densities, especially in the case of Model (2) for $\mathrm{C}_{5} \mathrm{O}$, do not coincide with the typical gas density for molecular clouds such as TMC-1. Indeed, Model (2) is able to reproduce the $\mathrm{C}_{5} \mathrm{O}$ integrated intensities for $n=[1-4] \times 10^{4} \mathrm{~cm}^{-3}$ only within confidences greater

[^3]Table 4. Column densities $\left(\mathrm{cm}^{-2}\right)$ and $\mathrm{C}_{3} \mathrm{O} / \mathrm{C}_{5} \mathrm{O}$ abundance ratios computed using both models in comparison with the data reported in the literature.

| Molecule | Model (1W/E) | Model (2) | Observation* |
| :---: | :---: | :---: | :---: |
| $\mathrm{C}_{3} \mathrm{O}$ | $[3.8-5.9] \times 10^{11}$ | $[4.8-6.8] \times 10^{11}$ | $[1.2 \pm 0.2] \times 10^{12}$ |
| $\mathrm{C}_{5} \mathrm{O}$ | $[8.4-9.4] \times 10^{9}$ | $[1.1-1.3] \times 10^{10}$ | $[1.5 \pm 0.2] \times 10^{10}$ |
| $\mathrm{C}_{3} \mathrm{O} / \mathrm{C}_{5} \mathrm{O}$ | $40-70$ | $37-62$ | $80 \pm 2$ |
| * stands for Cernicharo et al. (2021b) |  |  |  |

than $90 \%$. Such contour plots correspond to $1.6 \times \sigma$ (Lampton et al. 1976) which is reasonably good for astrophysical modelling.

Concerning the $\mathrm{H}_{2}$ volume density, the models lead to very different values. For instance, using Model (1W) and Model (2) for $\mathrm{C}_{3} \mathrm{O}$, we derived $n=[0.2-10] \times 10^{4} \mathrm{~cm}^{-3}$ and $n=[1.5-10] \times 10^{4}$ $\mathrm{cm}^{-3}$, respectively adopting a confidence level of $90 \%$. In the case of $\mathrm{C}_{5} \mathrm{O}$, Model (1E) suggests $n=[0.32-10] \times 10^{4} \mathrm{~cm}^{-3}$ whereas Model (2) predicts $n=[3.12-10] \times 10^{4} \mathrm{~cm}^{-3}$. Calling back the fact that a volume density of $\sim 4 \times 10^{4} \mathrm{~cm}^{-3}$ is often used in the literature for TMC-1, we can affirm that Model (2) better constrains the physical conditions.

Assuming a volume density of $4 \times 10^{4} \mathrm{~cm}^{-3}$, and a gas kinetic temperature of $10 \pm 2 \mathrm{~K}$ and a confidence level of $90 \%$, Model (2) leads to column densities of $[1.5-8.2] \times 10^{11} \mathrm{~cm}^{-2}$ and $[1.1-$ $1.3] \times 10^{10} \mathrm{~cm}^{-2}$ for $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$, respectively. The large interval obtained in the case of $\mathrm{C}_{3} \mathrm{O}$ can be reduced to $[4.8-6.8] \times 10^{11} \mathrm{~cm}^{-2}$ adopting a confidence level of $20 \%$. Therefore, we compare in Table 4 the results obtained for $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ adopting for each molecule the best fit (i.e. confidence levels of $20 \%$ and $90 \%$, respectively). Model (1W/E) underestimates the column densities derived using Model (2) by $20-30 \%$ whereas the $\mathrm{C}_{3} \mathrm{O} / \mathrm{C}_{5} \mathrm{O}$ abundance ratios differ only by $\sim 10 \%$. Therefore, the greater the rate coefficients are, the smaller the column densities are.

With respect to the observations, shown in the fourth column of Table 4, Model (2) underestimates the column densities by up to $25 \%$ and accordingly the abundance ratio by up to $50 \%$. These differences may come from the fact the observational spectra were analysed by mean of rotational diagram (Cernicharo et al. 2021b) whereas non-LTE calculations (Model (2)) are used in this work. An alternative source of bias is the omission of the filling factor in this work but its inclusion could also increase the disagreement. However, exact determination of column densities is beyond the scope of this work, but it can be done using the new rate coefficients and a more sophisticated model.

## 4 CONCLUSION

Integral inelastic cross sections of $\mathrm{C}_{3} \mathrm{O}\left(\mathrm{C}_{5} \mathrm{O}\right)$ induced by collision with He were determined using the exact close-coupling quantum mechanical approach for total energies up to 750 (650) $\mathrm{cm}^{-1}$. The thermal average of the cross sections by mean of the Maxwell-Boltzmann velocity distribution lead to downward rate coefficients for temperatures up to 100 K . Typically, we computed collisional rate coefficients for the 31 low-lying rotational levels of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$. The comparison of the collisional data of these molecules with those of $\mathrm{HC}_{3} \mathrm{~N}$ (Green \& Chapman 1978; Wernli et al. 2007) and $\mathrm{HC}_{5} \mathrm{~N}$ (obtained using equation 4) revealed that the excitation of $\mathrm{HC}_{n} \mathrm{~N}$ is much stronger than that of $\mathrm{C}_{n} \mathrm{O}$.

We also performed non-LTE radiative transfer calculations by mean of the RADEX computer code using the different sets of collisional rate coefficients mentioned above. We showed that the use of the scattering data of $\mathrm{HC}_{n} \mathrm{~N}$ instead of the actual ones can lead to LTE for gas densities as low as $\sim 10^{4} \mathrm{~cm}^{-3}$ and $\sim 10^{3} \mathrm{~cm}^{-3}$ for
$\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$, respectively. This behaviour is a direct consequence of the dominance of the $\mathrm{HC}_{n} \mathrm{~N}$ collisional rate coefficients over those of $\mathrm{C}_{n} \mathrm{O}$.

For the analysis of the $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ emission lines detected towards TMC-1 (Cernicharo et al. 2021b), the use of $\mathrm{HC}_{n} \mathrm{~N}$ as template for $\mathrm{C}_{n} \mathrm{O}$ underestimates the column densities by up to $30 \%$. Concerning the interpretation of the observational spectra, our nonLTE modelling which is based on the actual $\mathrm{C}_{n} \mathrm{O}$ collisional rate coefficients reduced the column densities reported by Cernicharo et al. (2021b) down to $25 \%$ and accordingly the $\mathrm{C}_{3} \mathrm{O} / \mathrm{C}_{5} \mathrm{O}$ abundance ratio down to $50 \%$. Nevertheless, further non-LTE modellings that take into account the source size and the telescope efficiency are needed to draw a more consistent conclusion.

## CONFLICTS OF INTEREST

There are no conflicts to declare.

## DATA AVAILABILITY

The data underlying this article are available in the article. We did not consider the isotopic substitution in this work but the collisional rate coefficients of any isotopologue of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ can be obtained upon request to the authors.

## APPENDIX A: FULL SET OF THE STATE-TO-STATE INELASTIC COLLISIONAL RATE COEFFICIENTS

In this section, we present the variation of state-to-state rate coefficients of $\mathrm{C}_{3} \mathrm{O}$ and $\mathrm{C}_{5} \mathrm{O}$ induced by collision with He for temperatures of up to 100 K . For both collisional systems, the rate coefficients increase with the temperature increase. Apart from the $1 \rightarrow 0$ deexcitation, minor differences (less than a factor of 2 ) exist between the other $\Delta j=1$ transitions especially at high temperature where they are all piled up. Despite these similarities, one can see that the $\mathrm{C}_{5} \mathrm{O}$-rate coefficients increase as a function of $j$ whereas the transitions are mixed in the case of $\mathrm{C}_{3} \mathrm{O}$.

This paper has been typeset from a $\mathrm{T}_{\mathrm{E}} \mathrm{X} / \mathrm{LA} \mathrm{T}_{\mathrm{E}} \mathrm{X}$ file prepared by the author

Figure A.1. Temperature dependence of rate coefficients of $\mathrm{C}_{3} \mathrm{O}$ (up panel) and $\mathrm{C}_{5} \mathrm{O}$ (low panel) in collision with He for $j \rightarrow j-1$ transitions, with $1 \leq j \leq 30$.
